A Review of Major Implications of the *O'Connor v. Donaldson* Decision

BY LOUIS E. KOPOLOW, M.D.

Although the Supreme Court's decision in O'Connor v. Donaldson *is narrow from the legal perspective, it will have wide clinical applications for psychiatry if it reflects a trend in future court decisions. The author assesses the impact of this decision on the mental health profession in terms of the issue of dangerousness as grounds for involuntary commitment for psychiatric treatment, the principle of least restrictive alternative to hospitalization, the question of adequacy of treatment in light of the absence of nationally defined standards, and the personal liability of physicians for their professional actions.*

THE O'CONNOR V. DONALDSON DECISION (1, 2) marks the first time that a Supreme Court decision recognized the legitimacy of judicial involvement in activities previously considered to be the exclusive domain of psychiatrists. It also marks the first review by the court of the judiciary process by which an individual is civilly committed to a state hospital. In this article I will attempt to assess both the clinical and forensic implications of the decision and address some possible programmatic outcomes.

HISTORICAL BACKGROUND

Kenneth Donaldson, a 67-year-old ex-patient of the Chattahoochee State Hospital in Florida, successfully waged a legal battle for his freedom in the Supreme Court of the United States. Donaldson was initially committed to the hospital in 1957 at the request of his parents, who were concerned about his mental state. Despite his repeated pleas that he was not dangerous or insane and requests for court intervention, Donaldson remained confined at the hospital for 15 years. Attempts to obtain his release by a friend and by workers at a Minnesota halfway house were blocked by Donaldson's doctor. In 1971, after the retirement of Dr. J.B. O'Connor, clinical director and later superintendent of the Chattahoochee State Hospital during Donaldson's confinement, Donaldson was released from the hospital.

A federal court jury awarded Donaldson $38,000 in damages for the invasion of his civil rights by Dr. O'Connor and Dr. John Gumanis of the hospital staff. This decision was upheld by the U.S. Court of Appeals for the Fifth Circuit and was appealed by O'Connor to the Supreme Court, which heard the case on January 15, 1975. The Supreme Court ruled in favor of Donaldson's claim that his constitutional right to freedom had been denied by O'Connor but remanded the case to the lower court on the issue of damages.

ASPECTS OF THE CASE

The importance of the *O'Connor v. Donaldson* decision is reflected in the holdings of the case (the conclusion of law reached by the court as to the legal effect of the facts of the case), the dicta of the case (opinions of a judge that do not embody the resolution or determinations of the court), and the significance of the issues in law and mental health touched on by the suit. The holdings in a Supreme Court decision have the force of law everywhere in the United States, but the dicta merely indicate the underlying philosophy behind the decision and give some indication of how future suits might be handled by the court.

The holdings of the Supreme Court's decision on June 26, 1975, were narrow in the legal sense; however, the dicta and issues examined have the potential to produce wide-ranging philosophical and programmatic effects on the providers and recipients of mental health care in future litigations. This potential impact on the mental health system can best be understood by examining four important issues: 1) the issue of dangerousness as grounds for involuntary commitment, 2) the principle of least restrictive alternative to hospitalization, 3) the question of adequacy of treatment, and 4) the personal liability of physicians for their actions.

Dangerousness and Commitment

The term "dangerousness" has frequently been used in legal and psychiatric circles to describe the

Dr. Kopolow is Staff Psychiatrist for Patients' Rights and Advocacy Programs, Division of Mental Health Service Programs, National Institute of Mental Health, Alcohol, Drug Abuse, and Mental Health Administration, 5600 Fishers Lane, Rockville, Md. 20852.

The opinions expressed in this paper are those of the author and do not necessarily reflect the views of the Alcohol, Drug Abuse, and Mental Health Administration.

concept of likely or actual harmful acts directed either at oneself or others. The limited holding of the court in *O'Connor v. Donaldson* is that "a State cannot constitutionally confine, without *more* [emphasis added], a non-dangerous individual who is capable of surviving safely in freedom by himself or with the help of willing and responsible family members or friends."

This ruling does not directly apply to those who might be considered dangerous by a psychiatrist, to those who might be dangerous to themselves, or to those who are incapable of surviving without assistance. Even more restrictively, it does not apply to individuals who are confined and given something more, presumably certain forms of treatment, even though they might be quite capable of surviving and present no threat to the safety of others. The court also seemed to sanction a broad definition of dangerousness as applied to civil commitment when it declared the following dicta:

> Of course, even if there is no foreseeable risk of self-injury or suicide, a person is literally dangerous to himself if for physical or other reasons he is helpless to avoid the hazards of freedom either through his own efforts or with the aid of willing family members or friends.

Such a definition might permit the continued hospitalization of organically impaired mentally ill individuals (those with organic brain syndrome) who, although they are not dangerous, are not able to avoid the "hazards of freedom." It remains for future court decisions to clarify this issue.

The Supreme Court's decision addressing the issue of dangerousness and confinement will have a rather limited effect on the mental health system. Despite some early predictions that thousands of patients would be released from state hospitals as a result of the rulings, according to a telephone survey of selected state mental health facilities conducted in August 1975, it is possible that only a very limited number of individuals meet the requirements of 1) being nondangerous, 2) receiving only custodial care, 3) able to survive the hazards of freedom through the aid of family or friends, and 4) held involuntarily in a facility. Patients who meet all of these criteria should be discharged quickly.

From the clinical and forensic psychiatric perspective, the *O'Connor* decision regarding dangerousness poses some very difficult problems. The state of the art is such that psychiatrists and other mental health professionals can describe behavior and offer dynamic theories about the etiology of emotional problems in court reasonably well, but they have considerable difficulty agreeing on diagnoses and predicting such future behavior as dangerousness or even the ability to "survive the hazards of freedom."

Predictions of dangerousness are with few exceptions predictions of rare or infrequent events for which there are no reliable base rates. As noted in the APA task force report *Clinical Aspects of the Violent Individual* (3), even if an index of violence proneness could be developed that correctly identified 50% of the individuals who will commit violent acts, the continued employment of such an index would identify 8 times as many false positives as true positives.

In spite of the difficulty in predicting future behavior, the *O'Connor* decision seems to be moving the courts in the direction of requiring a determination of dangerousness as the sole grounds for involuntary commitment. The potential of this trend raises some very serious philosophic questions about the participation of psychiatrists in the court system. If the psychiatrist's prediction of dangerousness is little more reliable than a layman's judgment of whether an individual will commit a criminal act, the use of criteria for involuntary commitment based on the prediction of dangerousness is as inappropriate in the mental health sphere as preventive detention is in the legal system. The mental health and legal systems must therefore determine what if any grounds are sufficient to involuntarily commit an individual for treatment and what minimum degree of reliability should be required for such commitment (4). If psychiatrists participate in proceedings involving involuntary commitment, they should make known at the outset the problems inherent in any prediction of dangerousness.

Least Restrictive Alternative

Another issue raised by the court's decision in *O'Connor* concerns the nature of the treatment that a patient receives and the location at which he receives it (hospital versus community). The court acknowledged that states have a legitimate interest in providing care and assistance to patients, but it also declared that the patients' preferences should be recognized as well. The court expressed the following dicta:

> The mere presence of mental illness does not disqualify a person from preferring his home to the comforts of an institution. Moreover, while the States may arguably confine a person to save him from harm, incarceration is rarely if ever a necessary condition for raising the living standards of those capable of surviving safely in freedom.

This section of the *O'Connor* decision will very likely produce controversy on two gounds. The first involves the question of whether an individual's mental status is of such importance to the state that his condition justifies intervention and potential deprivation of freedom. The second question is whether the decision has any bearing on the concept of least restrictive alternative to hospitalization.

The court's assertion that a state may not confine an individual for the purpose of raising his living standards reflects a changing philosophy about both mental illness and the practice of psychiatry. For hundreds of years many have believed that mental illness categorically prevents an individual from accurately perceiving reality and making reasoned judgments. Therefore, it was considered the state's duty according to

the principle of parens patriae to take care of such afflicted individuals, treat them for their illnesses, and protect society from their potentially harmful actions (5).

Consistent with this legal view has been the widely accepted psychiatric view that life and health, or physical and emotional well-being, are at the pinnacle of any hierarchy of values and should be maintained at any cost—even if the cost is a considerable loss of liberty for the individual whose health is at stake. A corollary to this position is the belief that madness and other forms of mental illness are diseases or processes that so impair an individual's judgment and capacity for responsible action in relation to himself and others that his statement of his own will is no longer valid. When the patient declares that he refuses hospitalization and treatment his wishes might very well be discounted and viewed as symptoms of his mental illness.

A countervailing philosophy is shared by a growing number of lawyers and mental health professionals concerned with civil rights. This view maintains that although a person's physical and mental health are important, they are not necessarily of the highest value, and that the freedom of the individual to place a higher value on other things should be respected. Those espousing this view maintain that what is called "mental illness" is not a process that necessarily interferes with or invalidates a person's will or lessens his responsibility to himself and others (6). Even a psychotic individual should have his wish to live at home rather than in a state mental hospital taken into consideration by the judges and psychiatrists who determine his fate.

The Supreme Court's decision in *O'Connor* reflected the view that confinement that is not demonstrably necessary and consistent with the principle of using the least drastic means necessary would not be sanctioned. Justice Stewart cited *Shelton v. Tucker* (7), in which it was noted that even when the government has shown that it has a valid reason or purpose for limiting or overriding an individual's constitutional rights, it must still show that the means it has chosen to accomplish that purpose will not limit the individual's rights any more than is absolutely necessary.

The court's movement toward a standard of ability to survive and the expectation that the least drastic means of treatment will be used will have the potential of producing some significant changes in psychiatric practice. The psychiatrist will have to modify his approach to involuntary treatment of nondangerous individuals and seek to encourage rather than coerce patients to follow a recommended regimen. In addition, least restrictive alternatives to hospitalization must now become a major consideration in the development of any proposed treatment plan.

The community-based least restrictive alternative approach to treatment might be given a boost by such court decisions as *O'Connor v. Donaldson* if the phrase "willing and responsible family members or friends" is interpreted as applying to such facilities as community mental health centers. Some legal experts (8) have raised the issue of whether the inadequacy of these centers to meet the demands placed on them or the nonexistence of these centers might be used as an excuse for confining an individual in an inpatient setting because he might be viewed as helpless to avoid the hazards of freedom. Another point affecting community-based treatment that needs further clarification concerns the term "willing." Although the Supreme Court declared in *O'Connor* that "mere public intolerance or animosity cannot constitutionally justify the deprivation of a person's physical liberty," one must wonder if such existing criminal laws as vagrancy or such civil statutes as zoning codes might be used to remove the mentally ill from the community. One example of this possibility is the suit of *Stoner v. Miller* (9) in Long Beach, N.Y.

Adequacy of Treatment

Another issue raised by the *O'Connor* decision that will likely be reflected in future court decisions concerns the definition of what should constitute adequate treatment. The court declared, "There is, accordingly, no occasion in this case to decide whether the provision of treatment, standing alone, can ever constitutionally justify involuntary confinement or if it can, how much or what kind of treatment would suffice for this purpose?"

Although the court thus avoided the question of whether the provision of treatment would be acceptable grounds for commitment, it expressed the dicta that "it is plainly unacceptable to suggest that the courts are powerless to determine whether the asserted grounds [treatment] is present." Some have argued that the court's statement in this instance opens the door for future judicial decisions as to what does or does not constitute adequate treatment. Another view is that the court did not refer to a judicial prerogative of determining whether the treatment given represents the best possible care but only if such treatment is possible (10).

Whichever turns out to be the accurate perception of future court rulings, it is clear that the mental health profession's role will undergo considerable change. No longer can the professional base his decisions as to the most appropriate treatment modality solely on clinical grounds. He must become cognizant of such issues as whether the patient will be viewed as dangerous by a judge or jury, whether the recommended program will be considered adequate treatment or even treatment, and whether he will be considered liable for denying the patient his constitutional rights if he continues to hold him in the hospital because he considers him dangerous if a future court hearing finds the patient not dangerous.

Other concerns for the physician will be whether he has followed due process procedures or obtained truly informed consent from the patient and what his liability will be if he releases an individual because he seems to meet the *O'Connor* criteria but the patient later com-

mits a dangerous act (11). If past trends continue, psychiatrists would rather refuse to treat involuntary patients than face the risks of litigation. State facilities, many of which are already overcrowded and understaffed, may find that mental health professionals, who are already feeling uncomfortable about treating involuntary patients, may be even less willing to work in such situations in the future as a result of recent litigation.

Part of the dissatisfaction of mental health professionals in various state and public hospitals is that the quality of treatment and care provided in these institutions is not as high as it should be. In the absence of nationally accepted standards, each state and sometimes each hospital can determine the nature of the care to be provided. The courts have felt justified in moving into the vacuum of lack of national standards to assure the rights of involuntarily committed mentally ill individuals. In cases such as *Wyatt v. Stickney* (now known as *Wyatt v. Aderholt*) (12–14) and *Welsch v. Likins* (15), the judges have consulted with various professional organizations, taken expert testimony, and come up with what they considered minimum standards. These standards tend to be more of the mortar and bricks and staff:patient ratio variety than to deal with actual quality of treatment.

For example, Judge Johnson in the *Wyatt* case handed down a two-part order on April 13, 1972, that set standards for mental disorder and mental retardation facilities and provided a detailed program for implementation (13). These minimum standards promulgated by the court include, among others, the following: a provision against institutional peonage; a number of protections to ensure a humane psychological environment; minimum staffing standards; provision for a human rights committee at each institution; detailed physical standards; minimum nutritional requirements; a provision for individualized evaluations of residents, habilitation plans, and programs; minimum staff:patient ratios; and a requirement that every mentally impaired person has a right to the least restrictive setting necessary for treatment.

The relative inability of psychiatrists and other mental health professionals to demonstrate the relationships among hypothesized etiologies of illnesses as well as their responses to treatment has impeded the development of agreed-upon standards of quality care and treatment and forced closer assessment of the nature of the activities mental health professionals can perform (16). To the extent that the mental health professions can become accountable and responsible for the assessment of need through prescreening, continuous monitoring of treatment, and evaluation of aftercare programs they can be freed from the restrictions and limitations of externally imposed standards.

The increasing pressures of the courts in such decisions as *O'Connor* will begin to move the mental health field into more intensive review of its activities and the development of acceptable standards (8). Although the initial response of mental health professionals might be to consider total withdrawal from law and mental health (no court involvement, no treatment of involuntary patients, etc.) it is to be hoped that this will be only a momentary reaction.

As a physician, the psychiatrist recognizes that his primary duty is to help the sick. Therefore, although he may resent and disagree with the encroachment of the law on what he has traditionally seen as his domain, he will continue do his job as best he can. The psychiatric profession should clearly explain to the courts what it can and cannot do in diagnosing and treating a patient and avoid the trap of being considered omniscient or omnipotent. The court, on its part, must realize that in the overwhelming number of interactions between patient and doctor the intent is to help, not harm, the recipient of care. Only through a realistic understanding of the goals and capacities of mental health professionals can the courts make appropriate determinations concerning such issues as grounds for commitment, the nature of quality care, and physicians' liability.

Physicians' Liability

One of the issues of the *O'Connor* decision that produced great interest among American psychiatrists is the fact that Donaldson not only sued for release but also sought money damages against his doctors. Due to the inexactness of medical science, the severe clinical repercussions for error in treatment, and the detrimental effect on their practices because of bad publicity, physicians as a group tend to be fearful of lawsuits. Donaldson's suit was particularly frightening for physicians because the nature of his charges (violation of his constitutional right to liberty) would obviate the possibility that malpractice insurance could cover any part of the damages. The charge also introduced a new area of accountability for which psychiatrists are unprepared.

Federal law provides that monetary damages are a proper remedy when a person is deprived of civil rights by someone under "cloak of State law." The Supreme Court did not uphold the assessment of monetary damages against O'Connor, but it declared that the issue should be reexamined by the circuit court in light of the new immunity standards enunciated recently in *Wood v. Strickland* (17):

> Whether O'Connor knew or reasonably should have known that the action he took within his sphere of official responsibility would violate the constitutional rights of Donaldson or if he took the action with the malicious intention to cause a deprivation of constitutional rights or other injury [to Donaldson] (2).

The Supreme Court qualifier "for purposes of this question, an official has, of course, no duty to anticipate unforeseeable constitutional developments," seems to indicate that the court is leaning toward the view that O'Connor should not be held liable. However, it clearly puts physicians on notice that from now

on if they confine or retain in custodial care a person who is not dangerous to himself or others and is capable of living safely in an available community alternative, even if he requires some support, they may be held liable for money damages. This decision is another warning to psychiatrists that they must reexamine their activities in light of evolving constitutional developments and not assume that their previous role as instruments of the state's parens patriae activities will continue unchanged.

CONCLUSIONS

As noted in the beginning of this paper, the *O'Connor v. Donaldson* decision is narrow from the legal perspective, but it will have wide clinical implications if it reflects a trend in future court decisions. The court's recent movement into this area after so many years of all but ignoring involuntarily committed mentally ill patients signals the need for a reexamination of mental health activities and closer cooperation and understanding between the legal and mental health systems. Only when the mental health profession fully understands what the court's expectations are concerning its relationship with patients and the court comprehends the potential and limitations of psychiatry vis-à-vis patients can the needs of both fields be adequately served.

On the issue of dangerousness, the court should be aware that even mental health professionals, who consider themselves students of behavior, have considerable difficulty predicting dangerousness. Therefore, to use dangerousness as the primary grounds for involuntary commitment is to place a heavy burden on a slender reed.

On the issue of least restrictive alternative, most mental health professionals would applaud closing antiquated state hospitals and replacing them with community-based alternatives. However, it remains for the government to consider mental health a sufficient priority to allocate the needed funds. Until such time, "least restrictive alternative" may simply be rhetoric for no treatment at all.

Concerning adequacy of treatment, the mental health profession should not be cowed by the beginning of court intervention in this area, but it should recognize it for what it is—the court moving in to fill the vacuum of inadequate standards of care and treatment created by the mental health profession itself. In the past the courts promulgated standards of care only when such standards were entirely lacking or ignored. Although the courts would prefer that the mental health profession set adequate standards of its own, the trend in the future appears to be increasing involvement of the courts in improving the adequacy of care and treatment.

The concept of the liability of physicians for their actions is an old one, but it has a new twist in that psychiatrists can now be found liable for money damages for doing what they have been encouraged to do for hundreds of years, i.e., confining mentally ill individuals. How the mental health system and the legal system grapple with and attempt to resolve this and other issues will dramatically affect all aspects of the practice of psychiatry.

Marijuana Effects on Simulated Flying Ability

BY DAVID S. JANOWSKY, M.D., MARTIN P. MEACHAM, M.S., JACK D. BLAINE, M.D., MICHAEL SCHOOR, AND LOUIS P. BOZZETTI, M.D.

The authors studied the effects of marijuana intoxication on the ability of 10 certified airplane pilots to operate a flight simulator. They used a randomized double-blind crossover design to compare the effect of active versus placebo marijuana. They found that all 10 pilots showed a significant decrease in measurements of flying performance 30 minutes after smoking active marijuana. For a group of 6 pilots tested sequentially for 6 hours, a nonsignificant decrease in flying performance continued for 2 hours after smoking the active drug. The authors conclude that the effects of marijuana on flying performance may represent a sensitive indicator of the drug's psychomotor effects.

ALTHOUGH THE USE OF MARIJUANA by the young adult population of the United States has dramatically increased in the last decade, virtually no information is available concerning its use by airplane pilots (1–3). Our informal inquiry has revealed that "social" marijuana smoking is not an uncommon practice among pilots, some of whom reported that they have flown aircraft while "high" on marijuana. For this reason, we felt that it was relevant to study the effects of smoking social doses of marijuana on the ability to operate an airplane flight simulator.

METHOD

We studied the effects of marijuana intoxication on the ability of certified pilots to operate a general aviation model ATC-510 instrument flight simulator (Analog Training Computers, Inc.). Seven professional and 3 private male pilots were recruited for the study. All had smoked marijuana socially for several years. Their ages ranged from 21 to 40. Three could be described as infrequent marijuana users (at the time of the study they were smoking marijuana twice a week or less), and 7 could be described as moderate marijuana users (they were smoking marijuana three or more times a week).

The pilots were familiarized with four consecutive 4-minute "holding pattern" sequences requiring a total of 16 minutes' "flight time," which included maneuvers typically encountered in instrument flight (e.g., straight and level flight, turns, three-dimensional maneuvering, and radio navigation). These tasks require psychomotor coordination as well as such cognitive abilities as short-term memory, concentration, and orientation in time and in three-dimensional space.

As described in appendices 1 and 2, the first and fourth 4-minute flight sequences consisted of a standard holding pattern. The second and third sequences consisted of a standard holding pattern modified by incorporating altitude changes. A low level of "turbulence" was also added to all four sequences so that the pilot would be required to continually manipulate the controls to compensate for the effect of the turbulence. These changes were carefully chosen to demand a high level of flying skill to correctly complete each sequence.

After the 10 pilots had attained proficiency in operating the simulator and in performing the four specific flight sequences, marijuana containing 2.1% Δ-9-tetrahydrocannabinol (Δ-9-THC) was administered in a dose of .09 mg of Δ-9-THC per kg. One week before or after active drug administration, a matched placebo containing a nonpharmacological amount of Δ-9-THC was administered. The pilots smoked the active or placebo marijuana in a pipe for a 10-minute period using a standardized smoking technique that consisted of the following: 10 seconds of inhalation, 20 seconds of holding breath, 5 seconds of exhalation, and 5 seconds of normal breathing. A randomized double-blind crossover design was used for the administration of active and placebo marijuana.

Thirty minutes after smoking active or placebo marijuana the 10 pilots performed the flight sequences. Their pulse rates and their self-ratings of degree of intoxication were recorded at this time. For the self-rating of degree of intoxication, each pilot was asked to

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The marijuana and placebo used in this study were supplied by the National Institute on Drug Abuse of the Alcohol, Drug Abuse, and Mental Health Administration, Rockville, Md.

rate his "high" on an open-ended scale on which 10 was designated as his usual social high and 0 represented his normal state.

We videotaped each pilot's flight sequence after both active and placebo marijuana smoking as well as just before smoking to establish baseline levels. These videotaped 16-minute flights were analyzed at 10-second intervals for deviation from the standardized flight pattern, altitude deviation, and heading deviation. When appropriate, the course deviation indicator (CDI), a radio navigation instrument, was examined at 5-second intervals. Total heading, CDI, and altitude deviations were calculated for each 16-minute flight sequence for each subject.

In addition, the pilot's "major errors," defined as those which if committed in the actual flight situation would take the airplane out of its designated air space with potentially dire consequences (e.g., getting lost, fuel exhaustion, stalling, and gross altitude or navigational deviations), were transcribed from the videotaped sequence and summed. The pilots' "minor errors," defined as altitude deviations greater than plus or minus 100 feet or heading deviations greater than plus or minus 30°, were also observed on the videotape, transcribed, and totaled.

The performances of 6 of the pilots were also evaluated 2 hours, 4 hours, and 6 hours after smoking. Each of these pilots was used as his own control in analyzing the effects of active versus placebo marijuana in altering flying ability (by sign test).

RESULTS

Eight of the 10 pilots were able to distinguish the placebo from the active marijuana. The 2 who erred in identifying the drugs were the least experienced in using marijuana. Most of the pilots rated their level of intoxication after smoking the active drug as slightly greater than their usual social high.

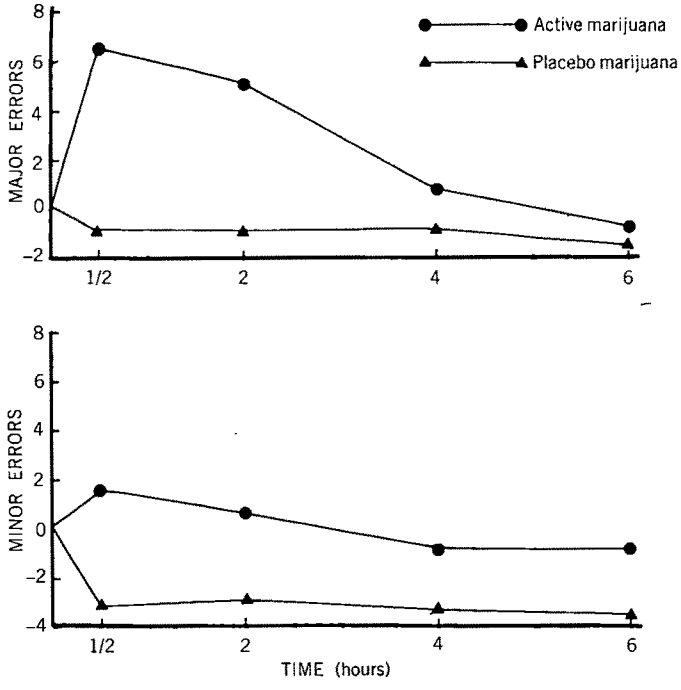
Average data for the entire group of pilots will be presented rather than data for individual performances because individual performance varied considerably from pilot to pilot and from variable to variable. As shown in table 1, the self-rating of degree of intoxication was significantly higher after smoking active marijuana than after smoking placebo ($p<.01$, sign test). Most of the pilots subjectively felt that the flying task was more challenging when they were intoxicated on active drug and did not believe that they had adequately compensated for any drug-induced deficiencies.This feeling was confirmed experimentally: all of the pilots evidenced a significant decrease ($p<.01$, sign test) in performance on all measurements evaluated during the flight after smoking active marijuana (see table 1).

The average pulse rate observed after placebo smoking was significantly lower than that observed after active marijuana smoking ($p<.01$, sign test) (see table 1). The entire group also demonstrated a statistically significant increase in the average number of major errors ($p<.01$, sign test) and minor errors ($p<.01$, sign test) after smoking active marijuana (see table 1).

TABLE 1
Average Pulse Rates, Self-Ratings of Degree of Intoxication, and Flight Performances of 10 Airplane Pilots 30 Minutes After Smoking Active or Placebo Marijuana

Item	After Smoking Active Marijuana	After Smoking Placebo Marijuana
Pulse rate	107	73
Self-rating of degree of intoxication*	10.5	0.5
Altitude (feet)**	2,615	680
Heading (degrees)**	627	332
CDI (units)**	100	42
Number of major errors	2.9	0.4
Number of minor errors	4.5	0.7

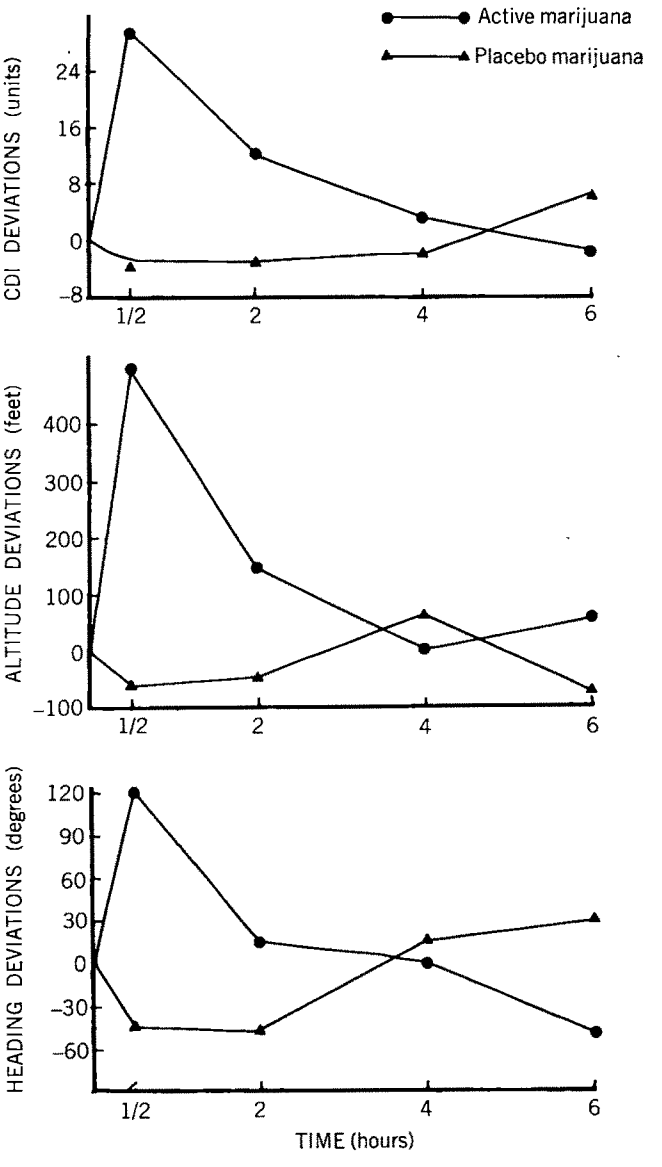
* 10=usual social high; 0=normal state.
** Values indicate total deviation from assigned flight path during entire 16-minute flight sequence.



Data were also obtained for 6 of the pilots over a 6-hour period after smoking active drug or placebo to elucidate the time course of the marijuana-induced deterioration in flying performance observed initially at 30 minutes. The flying performances of these 6 pilots were relatively consistent over the 6-hour period after smoking placebo, suggesting that neither learning nor fatigue significantly affected flying performance (by sign test). A decrease in flying ability, not statistically significant, was apparent for most of the 6 pilots 2 hours after smoking active marijuana, but this diminished in magnitude when compared with the statistically significant decrease noted at 30 minutes. The performances of all 6 of these pilots returned essentially to baseline levels by 4 hours (see figures 1 and 2).

DISCUSSION

These results have a number of implications, both for aviation medicine and for the understanding of marijuana's pharmacologic properties. The level of marijuana intoxication in these 10 pilots was generally self-rated as equal to the level they reached when they were socially intoxicated. The time course of the effects of marijuana also followed that encountered when marijuana is smoked socially (1, 4). The results indicate that smoking marijuana in doses used socially (5) causes significant deterioration in simulated instrument flying ability for at least 30 minutes in experienced pilots. The effect probably lasts for 2 hours and disappears in 4 hours.



Although the gross detrimental effects of marijuana appear to last for less than 4 hours, more subtle effects, detectable with more sophisticated equipment, may conceivably persist for longer periods of time in actual flight situations or more complex simulated con-

FIGURE 1
Average Number of Major and Minor Errors* of 6 Pilots After Smoking Active or Placebo Marijuana

*The number of errors represents the average number made by the 6 pilots after smoking compared with the average number they made before smoking (baseline levels) during an entire 16-minute flight sequence.

FIGURE 2
Average Deviations from Baseline Levels in Flight Performances of 6 Pilots After Smoking Active or Placebo Marijuana

ditions. Furthermore, the effect of altitude and pressure changes upon the performance of pilots intoxicated with marijuana represents a variable not measured in our experiment. Our data do not support safe instrument flight for at least 4 hours after smoking marijuana.

It is important to note that our flight task was relatively simple and that only a limited number of variables were evaluated. We did not record certain measurements, such as airspeed control, angle of bank, and rate of control movement, in our simulated flight situation, although these measurements were part of the simulated flying task. Although the results noted are quite dramatic, one must note that simulated flying differs from actual flying. Our pilots performed a memorized flight sequence; they had the instructions for the pattern in front of them at all times. In actual flight situations, instructions come sequentially from an Air Traffic Control (ATC) controller and must be accurately noted and repeated (i.e., read back) by the pilot. We believe that the performance of a pilot under these circumstances would be even more adversely affected by marijuana intoxication than in our experimental setting. The level of motivation to perform optimally and the ability to use some visual and kinesthetic cues and radar vectoring by ATC differ in actual flight situations from the simulated flight situation (6).

The deficiencies noted in the performances of our 10 pilots probably reflect marijuana's ability to affect a complex, learned psychomotor test involving memory, skill, concentration, sense of time, and orientation in three-dimensional space and in the performance of multiple complex tasks (5–10). Operationally, the simulated flying task is probably best described as a four-dimensional, complex cognitive tracking test.

It appears to us and to the pilots we tested that the major problems incurred in flying the simulator while intoxicated with marijuana involved certain specific factors. The most important appeared to involve marijuana's ability to affect short-term memory and sense of time. After smoking the active marijuana, the pilots often forgot where they were in a given flight sequence or had difficulty recounting how long they had been performing a given maneuver, in spite of the presence of written instructions and a stopwatch.

Marijuana also appeared to cause alterations in concentration and attending behavior: the intoxicated pilots would concentrate on one variable to the exclusion of other variables or perhaps attend to intrusive thoughts. As an example, several pilots noted that following a momentary lapse in attending to the flying task, they could not tell how long they had been flying or where they were located in the flight sequence. The realization that such inappropriate focusing had occurred seemed to lead to overcontrolling (oversteering) in an attempt to compensate for variables previously ignored and suddenly noted. Thus subjects exhibited a complete loss of orientation at times with respect to the navigational fix, resulting in grossly unpredictable flight performances. This loss of orientation occurred when the pilots were either daydreaming, "lapsing," or focusing on a certain part of their specified routine to the exclusion of other required activities.

We feel that the effects of marijuana on flying performance may represent a rather sensitive indicator of marijuana's psychomotor effects. Because of its multiple requirements, the task of flying may accentuate marijuana's cognitive disruptive effects (5–10) and thus prove useful in evaluating marijuana's interactions with other psychoactive drugs, such as alcohol and barbiturates, which also affect piloting performance (11–15). Thus the use of trained pilots to perform a complex psychomotor task may be a sensitive "bioassay" of marijuana's effects on cognitive functioning that has implications beyond those obvious to the safety of the airplane pilot.

APPENDIX 1
Standard Holding Pattern

Assuming a few simplifications, a standard holding pattern is oval in shape and is composed of four 1-minute segments, starting at a total elapsed time of 0 minutes, 0 seconds.

The first segment is a right-hand turn, performed at a standard turn rate of 3° per second. This turn is executed on reaching a navigational "fix," a locus defined variously by radio beacon, triangulation, and radar. Thus a standard turn lasting 1 minute results in a heading change of 180°, causing a course reversal (total elapsed time=1 minute, 0 seconds).

The second segment, called the "outbound leg," is a straight and level flight lasting 1 minute (total elapsed time=2 minutes, 0 seconds).

The third segment, also lasting 1 minute, is a right turn, ideally executed at the standard rate of 3° per second. However, the last portion of this turn, encompassing approximately the last 20 seconds, is normally used to align the aircraft on the proper course with respect to the navigational fix. The aircraft has now assumed the original heading (total elapsed time=3 minutes, 0 seconds).

The fourth segment of a standard holding pattern, called the "inbound leg," employs radio navigation to enable the pilot to fly the aircraft accurately to the initial navigational fix. This also takes 1 minute and concludes the standard 4-minute pattern (total elapsed time=4 minutes, 0 seconds).

In actual flight conditions, the pattern may be repeated many times and may incorporate climbs and descents to effect traffic separation, etc. In the experimental situation, the following criteria are employed: climbs—100% power, indicated airspeed (IAS)=120 miles per hour (mph), and climb rate=1,000 feet per minute; descents—50% power, IAS=160 mph, and descent rate=1,000 feet per minute; and standard turn rate—3° per second or 180° per minute.

APPENDIX 2
Specific Experimental Patterns

PATTERN 1

In the task demanded of the pilots, the first pattern flown is a standard holding pattern lasting 4 minutes, as defined in appendix 1. The pattern is flown at a target altitude of 2,000 feet.

PATTERN 2

On crossing the navigational fix at the conclusion of the first pattern (total elapsed time=4 minutes, 0 seconds), the flight plan calls for a climb of 1,000 feet to the 3,000-foot altitude at a rate of 1,000 feet per minute, while simultaneously executing a standard right-hand turn of 180°. Since the maneuvers in both geometric planes take 1 minute, the pilot is required to simultaneously level the aircraft at 3,000 feet

while rolling out of the turn on the appropriate reciprocal heading (total elapsed time=5 minutes, 0 seconds).

The aircraft is then flown on the reciprocal heading at a level altitude of 3,000 feet for 30 seconds, at which time (total elapsed time=5 minutes, 30 seconds) a descent of 1,000 feet to an altitude of 2,000 feet is begun. The standard holding pattern requires that a standard right turn begin 30 seconds later (total elapsed time=6 minutes, 0 seconds). The aircraft is to be leveled at 2,000 feet in the middle of this turn (total elapsed time=6 minutes, 30 seconds). The turn is completed after a total elapsed time of 7 minutes, 0 seconds, with the aircraft aligned with the inbound course to the navigational fix at an altitude of 2,000 feet. The aircraft then flies inbound toward the fix for 30 seconds at 2,000 feet (total elapsed time=7 minutes, 30 seconds), and a climb of 500 feet is instituted with the aircraft simultaneously reaching the navigational fix, leveling at 2,500 feet, and rolling into the standard right turn of the next pattern after a total elapsed time of 8 minutes, 0 seconds.

PATTERN 3

The first 30 seconds of this pattern is flown at an altitude of 2,500 feet while the standard-rate right turn is executed. At a total elapsed time of 8 minutes, 30 seconds, a climb of 1,500 feet to an altitude of 4,000 feet is begun. The aircraft is rolled out of the turn (total elapsed time=9 minutes, 0 seconds) and flown straight on the outbound leg while climbing to 4,000 feet. This altitude is reached at a total elapsed time of 10 minutes, 0 seconds, at which time a turn of 180° is started. Thirty seconds later (total elapsed time=10 minutes, 30 seconds) a descent of 1,000 feet to 3,000 feet is initiated. At a total elapsed time of 11 minutes, 0 seconds, the aircraft is once again positioned on the inbound course to the navigational fix. The pilot continues inbound toward the fix while continuing the descent to 3,000 feet. The descent is terminated at 3,000 feet (total elapsed time=11 minutes, 30 seconds), and the aircraft is assumed to reach the navigational fix at a total elapsed time of 12 minutes, 0 seconds.

PATTERN 4

The last pattern is a standard holding pattern flown at a level altitude of 3,000 feet. The experiment is terminated with the completion of this pattern after a total elapsed time of 16 minutes, 0 seconds.

ized by unremitting anorgasmia in the context of ceaseless extramarital relationships with older men is probably fixated at the oedipal level. Her disorder would not be informational or interpersonal. Psychological ontogenesis clarifies the fact that while this patient's difficulties may present as dissatisfaction with her spouse and appear to be interpersonal, they have the dynamic underpinning of a neurosis. To treat a neurotic disorder as an interpersonal one is to deny effective treatment.

TREATMENT TECHNIQUES

Considering the variety of sexual disorders, the spectrum of etiologies, and sexual ontogeny, no one treatment modality is sufficiently broad to cover all circumstances. Each treatment modality has its specific applications and limitations. In the following section I will discuss general categories of available treatment techniques; I have tried to be complete without being judgmental about efficacy, appropriateness, or compatibility with ethical standards.

1. *Dynamic psychotherapies*. As a general class, these techniques are based on psychoanalytic theory and observation. Core concepts include an ontogenetic psychological-developmental sequence, psychic structure, psychic conflict, defense mechanisms, the active unconscious, and transference development. Psychoanalysis, psychotherapy, and many group and family techniques are based in this framework.

2. *Behavioral modification techniques*. These techniques have their theoretical foundation in learning theory. Disturbed function is viewed as dependent upon disordered learning, conditioning, or habit. Behavioral modification through systematic desensitization and reciprocal inhibition is viewed as the therapeutic goal. The techniques developed by Masters and Johnson are classified here since they establish a hierarchy of sexual behaviors and use systematic desensitization as well as reciprocal inhibition. Related techniques include aversive conditioning, biofeedback, etc. Some forms of "masturbation therapy" (23) would be included here.

3. *Educational techniques*. This includes efforts at education as the primary focus. Lectures, audiovisual materials, the conjoint physical examination, and other methods are used in demonstrating sexual anatomy, physiology, or practice.

4. *Physical manipulation techniques*. The use of surrogates, the "sexological" examination (involving stimulation of the patient by the therapist), and techniques in which sexual manipulation is carried out or closely supervised by the therapist are included.

5. *Medical or surgical procedures*. The diagnostic physical examination and specialized surgical, pharmacological, hormonal, and neurological techniques are included in this category.

While not every specialist will be equally competent in each major category and may wish to avoid using some for ethical, medicolegal, or transference reasons, at a minimum the complete specialist will be familiar with the indications and contraindications for each technique and the indication for referral.

Educational techniques may be used for those patients whose malfunction or sexual hesitancy is related primarily to lack of information or experience. Behavioral modification techniques are useful for those patients whose disorders are in the interpersonal or situational realm or whose conflictual dysfunction is limited rather narrowly to the sexual disorder and is relatively free of continuing dynamic determinants from childhood conflict.

The dynamic psychotherapies are indicated for the treatment of neurotic, characterological, borderline, and psychotic disorders having sexual dysfunction as one component. This is not to say that behavioral or educational techniques may not be useful in a supplementary way, so long as the transference is protected by having them implemented by another therapist (7).

Medical and surgical techniques, of course, are clearly indicated in those disorders with an organic basis. Other treatment techniques may be necessary in a complementary or supplementary role. Directly manipulative techniques may conceivably be useful in some situations. However, transference and ethical considerations make their utility questionable.

ETHICAL STANDARDS

Ethics are extraordinarily important in the treatment of sexual disorders. In essence, ethical standards boil down to the rule that the patient is not exploited either vicariously or directly. This puts limitations on observation, recording, filming, and direct physical manipulation. Some practices, such as therapist participation in the sexual act, therapist nudity, and the use of surrogates are, to my mind, unethical. Perr (24) has outlined the potential legal hazards of the direct involvement of therapists in the treatment of sexual disorders. Aside from the potential medicolegal complications, direct therapist participation in sexual activity is unwise because it completely ignores the transference meaning of such involvement and the consequent deleterious effect on treatment (25).

DIDACTIC COMPONENTS OF TRAINING

Didactically, there are two major areas to be covered. The first deals with treatment techniques, and the second with developmental sexuality.

A firm grounding in the conceptual and theoretical bases of treatment techniques is essential. When the theoretical grounding is absent, treatment techniques are applied pro forma rather than with discrimination. For example, the Masters and Johnson techniques may be applied by rote, without the therapist's realization that they establish an anxiety hierarchy and trade

must be taken into consideration. As Stoller (13) observed, the syndromic classification of psychological disease states must be complemented by the dynamic and etiological.

Even though a complete outline of etiological factors in sexual disorder is beyond the scope of this paper, it is clear that not all cases of impotence are comparable. The same manifest disorder may have different etiological roots, which will determine the treatment most profitably employed. To return to the pneumonia analogy, specific treatment requirements are based upon the patient's inherent susceptibilities (which would vary if he is alcoholic, has obstructive bronchitis, etc.) and the particular pathogen involved (pneumococcus, staphylococcus, Klebsiella, etc.).

Some functional sexual disorders are based on lack of information, experience, and opportunity. There are others based on the interpersonal relationship and communication between partners. Still others are based on childhood experience, with arrest of psychological development. In my experience the most common pattern is some combination of all three. It is a discrimination of considerable finesse, at times, to decide which is the most important factor and the most amenable to intervention.

The etiological categories of sexual dysfunction outlined below are organized at a middle level, dynamically speaking, as a compromise between manifest symptomatology (at the most superficial level) and an individual psychogenetic formulation (at the most molecular). It is recognized that these clinical categories overlap and that there are gray areas between them. Nonetheless, this is a pragmatically useful scheme since it is directly related to the categories of available treatment techniques.

1. *Information-lack of experience-deficit sexual disorders*. These disorders are based in lack of experience, maladaptive education, or misleading information without significant basis in neurotic or characterological disorder or in the interpersonal aspects of the relationship.

2. *Interpersonally based sexual disorders*. These disorders are related to current interpersonal relationships or situations without significant basis in neurotic or characterological disorder.

3. *Neurotically and characterologically based sexual disorders*. These disorders have their basis in an internalized conflict, manifested by either symptoms or behavior, and are relatively independent of current interpersonal and cultural conditions. Excluded from this category are the sexual disorders based on a borderline or narcissistic modification of character.

4. *Borderline or narcissistically based sexual disorders*. These are sexual disorders having their basis in the relatively stable borderline or narcissistic personality disturbances (14–16). Many deviations have their basis in these personality modifications. In particular, the gender dysphoria syndromes are most often seen in severely borderline individuals.

5. *Psychotically based sexual disorders*. These are sexual disorders related primarily to the profound psychological regression and personality fragmentation of psychosis or prepsychotic states. The sexual disorders in these instances may involve any sort of sexual behavior, but the basic issue is the fragmented personality.

6. *Organically based sexual disorders*. These are disorders related to genetic, physiological, and/or anatomical impairment, with or without functional overlay. Impairment may be occasioned in fetal life, by disease states, as a complication of other treatment, or by trauma.

Complementing the mid-level classification of sexual disorders is the concept of developmental lines. In conceptualizing developmental lines, Anna Freud (17) spoke of an unfolding maturational sequence from infantile emotional and physical dependence to adult sexual and work relationships, stressing interplay among predisposition, environment, and already achieved levels of mastery and integration. A simplified developmental line for sexuality, with elements borrowed from a number of authors, is as follows:

1. Fetal development, with the differentiation of internal and external sexual structures, the establishment of cyclic versus acyclic gonadotrophin release, and active versus passive patterns of energy expenditure (18).

2. The establishment of satisfactory symbiosis as a basis for comfortable and trusting intimate human relationships (19).

3. "Separation-individuation," establishing the capacity to relate to another individual as a separate and real person (19).

4. Gender identity formation (20, 21).

5. The elaboration and working through of the oedipal, triangular, competitive relationship.

6. Disavowal of sexual drives during latency.

7. The resurgence of biological sexual drives with reproductive capacity at adolescence.

8. Later in adolescence, the consolidation of genital primacy as a basis for intimacy.

9. Marriage and the establishment of committed intimacy.

10. Reproduction and child rearing in which all the previous issues may be reworked.

(For a further elaboration of these developmental issues, particularly 5–10, see reference 22.)

The mid-level etiological classification system provides a general orientation to the broad spectrum of sexual disorders, whereas a firm grounding in developmental sexuality provides the best framework vis-à-vis the individual patient.

Sufficiently careful history taking to identify the developmental areas in which the individual patient had difficulty, became fixated, or was arrested will allow placement in the appropriate category of sexual disorder. For example, a female patient whose parents were divorced when she was age 5, whose mother subsequently had multiple lovers, whose adolescence was a model of propriety, but whose adult life is character-

shibboleths that are assumed to describe: 1) a problem area in some way intrinsically different from other emotional or physical disorders; 2) treatment techniques that may be applied across the board with little concern for differential diagnosis, etiology, or prognosis; and 3) a group of practitioners for whom traditional values of training and experience have only limited application.

As commonly used, the term "sex therapy" implies that the patient's "sex" can be treated with little concern for the complexities of constitutional endowment, physical health, developmental history, intrapsychic conflicts, or capacity for sublimation.

THE MEDICAL/PSYCHIATRIC APPROACH TO TREATMENT

A number of authors have addressed the issues of constitution, physical health, and psychodynamics in the treatment of sexual disorders.

Masters and Johnson have emphasized the physiological underpinning of sexuality (1) and the importance of this knowledge in the application of their treatment techniques (2). They have also stressed the importance of a screening or diagnostic physical examination.

Among the psychoanalytic authors, Kestenberg (7), Fink (8), and Stoller (9) have emphasized the continuing relevance of dynamic concerns in sexual disorders and have attempted to amalgamate physiological information and short-term techniques within the psychodynamic framework. On a more pragmatic level, Kaplan and Kohl (10) have emphasized the possibility of untoward reactions in patients receiving short-term treatment unless there is adequate consideration of the role of the sexual dysfunction in intrapersonal and interpersonal dynamics. Meyer and associates (11), in their application of the Masters and Johnson techniques, noted a tendency for transference to develop, intrapsychic conflict to be mobilized, and the more pervasive characterological and neurotic roots of sexual disorder to become apparent. These observations indicate that judicious treatment of sexual disorders requires due consideration of physical health, personal history, intrapsychic dynamics, and the current context of the individual's life.

THE MEDICAL CONTEXT

In a medical context there is emphasis on the distinction between treatment (with its medicolegal safeguards and long tradition of responsibility) and counseling, giving advice, or lending a sympathetic ear. A medical context implies familiarity with all categories of sexual disability, not merely one subclass of syndromes. A medical context implies that appropriate and skillful attention will be paid to the issues of evaluation, disposition, and prognosis. This implies the capacity to discriminate among organic conditions, functional conditions, organic conditions with a functional overlay, and organic conditions in which the functional aspect is not an overlay but an intrinsic part of the disease process. A medical context implies skill in a broad range of treatment techniques from the most elemental to the most sophisticated. A medical context also implies that based on evaluation, etiology, anticipated management problems, and prognosis, a treatment modality is selected that promises to have the best results in the individual situation. In other words, there is no a priori commitment to one treatment modality.

To emphasize the point, an analogy seems apt. The pneumonias usually require bed rest and hospitalization as common basic factors in treatment. On the other hand, the selection of particular antibiotic and supportive measures depends on an appreciation of distinct etiologies and prognoses. In general, gram-negative pneumonia does not respond well to simple penicillin.

THE SCOPE OF MANIFEST CLINICAL SYNDROMES

The disorders and problems that should be familiar to a medical subspecialist in the field of sexual disorders are as follows:

1. *The common sexual disorders*, e.g., impotence, premature ejaculation, anorgasmia, dyspareunia, vaginismus, and withdrawal from sexual activity.
2. *The uncommon disorders*, e.g., ejaculatory incompetence and sexual anesthesia.
3. *The paraphilias*, for example, exhibitionism, pedophilia, and voyeurism.
4. *The homosexual syndromes*, both male and female.
5. *The gender dysphoria syndromes*, e.g., so-called "transsexualism" and its variants (12).
6. *The physical developmental disorders*, for example, penile agenesis, hypospadias, and intersex conditions.
7. *Disease-related disorders*, including impotence secondary to diabetes or a temporal lobe disorder as well as some dyspareunias.
8. *The iatrogenic disorders*, i.e., those secondary to psychotropic or diuretic agents or surgery.
9. *The traumatic disorders*, e.g., penile or vulvar injuries.

ETIOLOGICAL CLASSIFICATION OF SEXUAL DISORDERS

The foregoing review of manifest disorders is useful for appreciating the spectrum of sexual disabilities. As medicine learned long ago, however, treatment cannot be based solely on the manifest presentation of disease. Etiological factors and the structural modifications occasioned by the pathological process also

Training and Accreditation for the Treatment of Sexual Disorders

BY JON K. MEYER, M.D.

The field of "sex therapy" is not defined by specific, limited techniques. Rather, it encompasses a subspecialty based on an understanding of psychodynamics and psychological development but requiring additional skills from other branches of medicine. Despite its breadth and complexity, sex therapy training is unregulated, with the public lacking the protection afforded by standardized training programs or certification. The author outlines the scope of sex therapy as a psychiatric and medical subspecialty and delineates the necessary clinical skills for the physician-practitioner.

THE PHYSIOLOGICAL research (1) and new treatment techniques (2) of Masters and Johnson created a healthy ferment in the conceptualization and treatment of sexual disorders. These researchers view sexual disorders as the result of poor education, unfortunate social circumstances, and unhappy interpersonal relationships. They view treatment in a didactic, educational, systematic desensitization framework, with the exclusion of the issues of psychodynamics and transference, the traditional preserves of psychiatry. Their enthusiasm, published results, deemphasis of psychodynamic factors, and nonpsychiatric background provided a model and a rationale for the treatment of psychologically based sexual disorders by a variety of different physicians and allied health professionals.

This process is illustrated by the recent formation of the Eastern Association for Sex Therapy, with membership open to the medical specialties, psychology, and the allied health professions. One purpose of this organization was to formalize standards for sex therapists through its admission requirements (3). The extent of the process is illustrated by the recent decision of the American Association of Sex Educators and Counselors to certify "sex therapists" rather than to accredit "sex counselors" (4). On the positive side, both organizations are concerned with the issues of credentials and accreditation in the field of "sex therapy," a field in which there are few guidelines and many abuses.

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Meyer is Director, Sexual Behaviors Consultation Unit, Johns Hopkins Medical Institutions, Baltimore, Md. 21205, and Assistant Professor of Psychiatry and Surgery, Johns Hopkins University School of Medicine.

There is no quarrel with the efforts of these organizations to establish credentials and standards of practice for their members and to certify that these standards are met. However, it is important to avoid what Romano called "false egalitarianism" that obscures "the differences in education, knowledge, skill, and responsibility between professionals and paraprofessionals in the interdisciplinary care of patients" (5, p. 433). General standards compatible with training and experience in the allied health professions are not sufficient standards for physicians.

The extent of poorly qualified or frankly unqualified therapist participation in the treatment of sexual disorders is largely known from anecdotal reports or from interviews with surrogates in the popular literature. In every locale, however, there are practitioners whose training and experience, not to mention ethical standards, are open to question. In a recent article Masters was quoted as saying, "of all the clinics in operation in the United States today, at best 50 might be considered legitimate. The rest are frauds" (6). Masters made a strong case for the necessity of medical coverage and responsibility as an irreducible minimum for legitimate clinics.

Medical coverage and responsibility are the minimal requirements for bona fide practice. The characteristics and standards of that medical practice, however, must be defined.

A problem in defining proper training and accreditation for physicians specializing in the treatment of sexual disorders is that the scope of the field is undefined. It is essential to reach a general definition of the field in order to know what one is training and is accredited *for*. After that, a training program and accreditation standards almost automatically fall into place. In certain centers the practice of sex therapy is limited to the treatment of couples using the techniques developed by Masters and Johnson. Other centers focus on physical disorders and use medical and surgical approaches. Still others view the sexual disorder as a secondary symptom and focus on neurotic or characterological features, using psychodynamic approaches. Some integration of these various approaches is clearly required.

"SEX THERAPY"

In attempting to define the field, the terms "sex problems," "sex therapy," and "sex therapist" immediately cause problems. These terms have become

heavily on systematic desensitization. Without this realization, the practitioner cannot select out those components of the method which are essential and those which are not, and modifications are made on personal whim rather than on considered judgment. Similar issues may be raised regarding dynamic techniques. Transference development, elucidation, and interpretation are designed to resolve pathological formations that are concretized in intrasystemic conflict. When intrasystemic conflict is minimal in comparison to the habitual or interpersonal aspects of sexual disorder, dynamic techniques are less useful and less cost effective than education or behavioral modification.

It is also essential to have a thorough grounding in the developmental aspects of sexuality, including psychosexual (intrapersonal and interpersonal), cultural, endocrinological, physiological, anatomical, and neurological factors. Didactic review would include fetal development, the intersex conditions, and related anomalies affecting sexual functioning (26); gender development (27, 28); the role of hormones (29, 30); anatomical factors in sexual relationships (31); physiological factors (1); and cultural aspects of sexual activity (32, 33). (These references are intended merely as examples of the sources that might be read and assimilated.)

CLINICAL COMPONENTS OF TRAINING

Clinical experience may be incorporated into residency training. Subspecialty training, however, is viewed here as requiring extended postresidency affiliation with an active program, allowing a focus on evaluation, diagnosis, prognosis, treatment selection, management, and treatment of a broad variety of sexual disorders, with extensive supervision. This may be done on a part-time basis, making it feasible for the physician responsible for his own livelihood.

ACCREDITATION

Membership in any of the organizations for sex therapists does not adequately fulfill the requirements for standards and experience for psychiatrists and other physicians. These standards cannot be sufficiently exacting by virtue of the broad membership. The organizational issues of accreditation for psychiatrists would need to be considered within the structure of the American Psychiatric Association or under the aegis of the American Board of Psychiatry and Neurology.

CONCLUSIONS

Medical sex therapy is not defined by specific techniques, such as those developed by Masters and Johnson. Rather, the field is defined by the required competence and orientation of the practitioner. As in other areas of medicine, the orientation of the practitioner is toward evaluation, differential diagnosis, prognosis, and treatment selection from among the available spectrum of therapeutic modalities. Suitable competence of the subspecialist in sexual disorders necessarily involves a broad basis in theoretical and developmental issues, as well as experience in treatment application.

Sexuality in its manifold aspects is at the very core of psychiatric practice. As Freud (34) observed in 1905, anyone who is in any way abnormal in mental life will also show an abnormality in sexual life. Clinical experience since then has confirmed that notion. Because of long clinical experience with such phenomena and a theoretical framework within which to conceptualize these findings, psychiatry is in a primary position to contribute to the treatment of sexual disorders. Psychiatrists, however, are also physicians. And within the framework of medical practice is the concept of having a therapeutic armamentarium to be used judiciously according to assessment of the patient.

Medicine, by virtue of its long concern with evaluation, prognosis, disposition, management, treatment, and follow-up, is the best arena for the treatment of sexual disorders. Within medicine the experience, theory, and broad perspective of psychiatry will allow leadership, if psychiatry will take it.

Change in 1976 Annual Meeting Site

The APA Executive Committee decided to move the May 10-14, 1976 APA Annual Meeting from Atlantic City to Miami, Florida, after hearing the APA Meetings Management Department report that it had ascertained that a major Atlantic City hotel had inadvertently committed several hundred rooms to another organization during the week the APA meeting was scheduled. This would have left APA with the unacceptable alternative of using a myriad of scattered small hotels in the Atlantic City area. It has been confirmed that Miami Beach can accommodate the meeting.

Further arrangements and developments will be reported in future issues of *Psychiatric News*.

The Family in Exile: Cuban Expatriates in the United States

BY RUBÉN D. RUMBAUT, M.D., AND RUBÉN G. RUMBAUT, M.A.

For the nearly one million Cuban exiles in this country, the ordeal of expatriation has meant anguish and uprootedness, challenge and accomplishment. Several factors account for the comparatively successful aspects of their struggle: relatively high occupational and educational levels, formation of vigorous communities that permit the maintenance of a positive ethnic consciousness and the creation of strong social ties, and effectively organized reception by the United States. Expatriation is always traumatic and produces "casualties," but mastery of the struggles it involves can lead to personal growth and expanded horizons. The Cuban expatriate experience shows that the influx of large numbers of refugees can be a creative and enriching process for both the host country and the individual refugee.

JANUARY 1, 1959, WAS the beginning of an accelerated, conflictual, and explosive political process on the island of Cuba. As a result of this process, an increasingly large number of Cubans who rejected the legitimacy of the new regime are now in exile. Seventeen years have passed, and the exodus has not ceased. Cuban expatriates (who now number more than a million) have taken refuge in all parts of the world, but the vast majority have come to the United States.

The magnitude of this radical dislocation of individuals and families should be considered in perspective. When the exodus began in earnest in 1960, the population of Cuba had just reached 6 million. Today there are more than 10 million Cubans, 9 million living on the island and the rest, mostly exiles and their offspring, living abroad. During this period, roughly 10% of the Cuban people have been severed from their homeland as political refugees.

According to James L. Canlin, Deputy Coordinator for Humanitarian Affairs, Office of Refugee and Migration Affairs, U.S. Department of State, 654,314 Cubans arrived in the United States from January 1959 to December 1974. For a variety of reasons (a discussion of which is beyond the scope of this paper), this official statistic probably underestimates the actual extent of the expatriation. Moreover, this figure obviously does not include the many thousands of Cubans who had come to the United States from the turn of the century through 1958, nor the children born to the exiles from 1959 to date, nor the refugees who have come during 1975 and early 1976. The population of individuals of Cuban origin in the United States consists of between 100,000 and 200,000 families dispersed throughout the 50 states and Puerto Rico. Areas with the largest Cuban population are southern Florida, New York-New Jersey, southern California, and Illinois.

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Rumbaut is Associate Professor of Psychiatry, Baylor College of Medicine, Houston, Tex., and Director, Day Hospital, Veterans Administration Hospital, 2002 Holcombe Blvd., Houston, Tex. 77031. Mr. Rumbaut is Lecturer, Department of Sociology, San Diego State University, San Diego, Calif.

THE EXILE PROCESS

The experiences that led large sectors of Cuban society into expatriation were complex. The best available research, conducted by a group of American sociologists (1), identified seven major types of motives: 1) temporary imprisonment, 2) fear or threat of imprisonment, 3) harassment and persecution, 4) forcible attempts at integration into the revolution, 5) loss of jobs, possessions, or sources of income, 6) disagreement with governmental action deemed arbitrary, and 7) refusal to accept a Communist regime. Thus a wide range of pragmatic and ideological considerations characterized the decision to leave Cuba, including a perceived threat to basic religious values, family life, and liberal democracy. In pointing to the political character of the Cuban exodus, Fagen and associates stressed that,

> It would be a mistake to think of the exiles as alienated from their homeland in the sense that we think of certain youth, minorities and intellectuals as alienated in other countries. . . . The typical refugee affirms a "higher loyalty" to Cuba, to *la patria*. . . . He is in exile from the government in power; he is in exile from Cuba only insofar as the Cuba that he knew and loved has, in his view, been betrayed and despoiled. (1, p. 103)

Chronologically, Cuban expatriates have come to the United States in four distinct phases:

1. January 1959 to October 1962: daily commercial flights between Cuba and the United States were terminated after the latter date.
2. October 1962 to December 1965: refugees arrived in small boats or through third countries.

3. December 1965 to April 1973: an airlift provided two daily flights from Varadero to Miami.

4. April 1973 to the present: refugees continue to arrive in the United States through third countries, in small boats, and from a backlog accumulated in some foreign nations.

The exiles who came during the first phase were disproportionately drawn from the urban middle and upper classes of Cuban society, including those in the higher educational and occupational brackets (2), whereas those who have arrived during the last decade have been increasingly representative of all sectors of Cuban society. However, the available data throughout have precluded any easy explanations of the exile process solely in terms of economic interests or any other unidimensional concept of a multidimensional problem.

From a psychosocial perspective, a recent study (3) has distinguished three types of expatriate groups: 1) those who hope for a quick return, typifying the early exiles (from whom the participants in the 1961 Bay of Pigs invasion were recruited), 2) those who escape from dangerous or uncertain circumstances, more numerous after the invasion and during the second phase, and 3) those who seek improved economic opportunities, more typical of later emigrants who evidence the frustration of their personal aspirations for the future. In general, according to this study, the first two types were "pushed out" by political conditions, whereas the third type was "pulled out" by economic concerns and the hope for self-advancement and a better life.

There are other alternatives to the classification of the refugees' experience that may help to underscore the diversity of these individuals and their circumstances. One study indicated, for example, that the adaptation process has been more difficult and demanding for Cuban women than men, particularly in the case of unaccompanied refugee women (4). Age is another important factor: children are more flexible, young and middle-aged adults have to assume an inordinate amount of responsibility, and older people generally do not have to work but are less flexible, sense the loss of their homes more acutely, and evidence a reduced capacity to learn a new language and achieve a satisfactory degree of autonomy.

One of the most dramatic groups of refugees consists of an estimated 15,000 children who came to this country without their parents (5). There were many reasons why this happened, but the primary explanation is bureaucratic: when many parents panicked and tried to take their families out of Cuba, children under 16 were permitted by the U.S. government to come on waivers of visas, while their parents were required, as is customary, to have visas. The Cuban government also made it easier for the very young and the very old to leave, while working adults or men of military age faced many more obstacles. As a result, hundreds of children remained separated from their parents, sometimes for several years. These children were placed in institutions, foster homes, relatives' homes, and orphanages in 110 cities in 40 states.

Despite their diversity, Cuban refugees (like all refugee groups) share in a common process of expatriation and subsequent adaptation. In this sense we can describe the refugee as a social type and discuss the prototypical experience of exile for analytical and heuristic purposes.

PSYCHOLOGICAL ELEMENTS OF THE EXILE EXPERIENCE

The refugee coming to a new country goes through an extremely complex and intense experience that, when analyzed, breaks down into numerous components. These components can, however, be described using as a metaphor Janus, the Roman god of beginnings. Janus was always depicted at the gate of the cities and had two faces, which enabled him to see in opposite directions simultaneously. This image illustrates the plight of the refugee. The face that looks back sees displacement, separation, uprooting, loss, nostalgia, and, in a certain sense, even death, because some things die inside us when we are forced to abandon our homeland without the possibility of returning at will. The face that looks forward sees new horizons, unknown environments, strangers with unfamiliar customs and languages, real and imaginary perils, a vigorous challenge to survive, adapt, and grow, and even the opportunity of constructing a new identity in sudden anonymity. Thus, psychologically speaking, the refugee's experience combines elements of premature death and rebirth, a peculiar process in which he is both conscious protagonist and conscious spectator.

A conflict of loyalties ensues from the moment the thought of departing enters the mind of the would-be expatriate. The decision to choose—or reluctantly accept—exile entails an inner agony between those forces that bind and those that expel a person from his land. After the initial decision is acted on, the dilemmas that accompany it persist for years. First and foremost one must survive, which channels the decisions and experiences of the refugee along available structures of opportunity. Then comes the agonizing arrangement of priorities, the careful selection among narrow options. Should one focus on an ideological struggle to the exclusion of everything else? Should one settle in Miami, the point of arrival for most refugees, or resettle elsewhere—an alternative that represents a sort of second exile? Is occupational retraining in one's field feasible, or must one switch occupations? How will one fulfill the obligations to family, work, and to a society that offers generous asylum? The choice seems to be "adaptation or ghetto" (6).

Forced uprootedness from one's community is the salient feature of exile. Azcárate (7) has described the psychiatric symptomatology of Cuban expatriates (when it is manifested) as an expression of an overwhelming sense of anxiety, depression, and inability to

cope with the emotional problems presented by the anomic circumstances of exile. This is primarily experienced as an attitude of helplessness, a feeling that nothing can be done. Separation from the family, length of exile, and return to Cuba are all beyond one's control, at least psychologically. The wish is to return to a Cuba that no longer exists.

In the first weeks of expatriation, mild paranoid attitudes (a carry-over) are relatively common; this is followed by a transient sense of relief, relaxation, and even euphoria. Then, the slow realization of the painful limitations and long struggles ahead begins; anxiety mounts and depression deepens. There are few refugees who do not bear deeply ingrained psychological scars. Still, a new path is slowly opened, much as an explorer cuts his way through a dark jungle toward distant filtered light. A shelter of some sort is found, a small income is secured, children register in school, and some acquaintances are made. From then on, the process is one of gradual rebirth.

Unexpected and paradoxical advantages attend the experience of exile. Culture shock deroutinizes the flow of everyday life. One feels strangely free of ties, attachments, social inanities, trivia, and the rituals of participation in countless formal and informal organizations that characteristically consume much time and effort. One discovers that old routines and conventions can be discarded and new perspectives and values can be incorporated. One suddenly recognizes common origins in the many shared elements of the new and the old culture. Indeed, it is one of the ironies of exile that the very circumstance of uprootedness permits a rediscovery of the familiar—of the family and of the most fundamental meanings and functions of human community. One encounters at once the universality and relativity of being human.

Perhaps a reactive overcompensation to the prolonged feelings of helplessness, sadness, loneliness, estrangement, and handicap—combined with added free time and the need to concentrate rigorously on "making it" in lean and austere circumstances—explains why, beyond the numerous casualties that this process inevitably produces, many of the "survivors" excel in their endeavors. All of their inner resources have been fully tested, their dormant qualities and potentials have been evoked, and their purposes and goals have been challenged. For those able to cope successfully with the exceptional demands, a more fulfilling and productive life may lie ahead. After all, a victory is rewarding in direct proportion to the amount of personal effort it requires. A refugee—devoid of citizen status, not belonging to any group, and lacking influence and connections, property and savings, and language and cultural skills—feels somehow alone and bare in an unconquered environment. He has to reconstruct his life, even to the point of learning to communicate again. If he eventually masters the environment, his self-reliance grows, and the strengthened motivation and sense of purpose will predictably exceed the average level.

The experience of a shared crisis may itself facilitate the development of a stronger family bond, affording a common cause around which a more lasting cohesiveness can be built within this interpersonal supportive family network. The children, who are still flexible, malleable, curious, and thirsty for discovery, adapt amazingly well. They learn the new language with no accent and the new customs without hesitation. We feel that it is a myth that bilingualism should be avoided during the period of transition. In fact, the Cuban student not infrequently rises to the top of his classes in spelling, grammar, reading, and writing in English, while keeping an adequate Spanish vocabulary. Penfield (8) has proposed the concept of the "uncommitted cortex" during childhood and encouraged people to learn different languages at an early age. This is in complete accord with our experience.

SOCIAL DETERMINANTS OF THE EXILE EXPERIENCE

For the Cuban exiles, the process of creating new beginnings has occurred not amidst stable conditions in the receiving society but amidst the social and political upheavals that have characterized U.S. history during the last 15 years. We can therefore identify diverse sources of stress. The exile process during the sixties and into the seventies in the United States constituted a double source of marginality and role strain—culture shock was combined with future shock, entailing not only the problem of adaptation to the new society but of coping with rapidly changing conditions that even its own native population found difficult to cope with. Further, these structural sources of stress have been reflected within the family in both the well-known generation gap and in parent-child conflict arising from differential rates of adaptation to the new culture. This "adaptation lag" may be manifested, for example, in a child's embarrassment over his parents' occasional cultural faux pas or in the parents' insistent expressions of concern over the child's increasing "Americanization." In some important respects, the clash of the exiled youth is not so much with the American culture as with the Cuban, particularly in situations where friendship networks consist almost exclusively of primary relationships with English-speaking peers. Such generational problems are accelerated by the coincidence of expatriation with a period of profound social conflict marked by the emergence of a broad spectrum of movements for social change. Psychosocially, the experience of exile has represented to the expatriate an extraordinarily stressful process of dislocation and relocation, loss and rediscovery, and uprootedness and new growth.

Structurally, however, the Cuban emigration to the United States has been called a "golden exile." Portes noted in his study of Cuban refugee families in Milwaukee (9) that "seldom has a foreign group come to the United States so well prepared educationally and occu-

pationally and seldom has this country received one so well." Portes suggests that the ideological congruence between the prevailing values of American political culture and those for which the exiles left their homeland is a factor that helps to account for this Cuban "success story," as the American press has termed it. More significantly, the organized reception accorded the refugees—including concerted community action by diverse national and local groups in Miami and government assistance made available since the 1961 founding of the Cuban Refugee Center—has provided an important source of initial support, resettlement aid, and other necessary help. Other mitigating factors include the exiles' prior proximity to and familiarity with U.S. society and their historical affinity with the large Spanish-speaking minority already present in this country. We view these as necessary but not sufficient conditions in accounting for the structural integration of this massive influx of Cuban exiles.

The development and maintenance of a strong sense of ethnic consciousness and ethnic community have been key social determinants of the adaptation process of Cuban exiles. Despite the patent situational differences between Cuban families in the teeming colony of "Little Havana" in Miami and those resettled elsewhere, Cuban communities throughout the United States have functioned as comparison reference groups for their members and, as one study of refugee families in New Jersey indicated (10), cushioned the loss of occupational status. They permit adaptation within a supportive network of ethnic relationships and affiliations and constitute sources of psychosocial gratification to the expatriate that are unavailable outside Cuban groups. The existence of Cuban communities sustains a singularly Cuban self-image. The proliferation and interplay of discrete aspects of traditional lifestyle—such as Cuban music, dress, literature, mass media, meeting places, celebrations, and even basic items of Cuban cuisine—contribute substantially to the maintenance of the group's symbolic identity under conditions that might otherwise have caused it to atrophy.

In the manner of a self-fulfilling prophecy, the exiles typically have brought a feeling of equality with their American counterparts and a conviction of their ability to adapt in this country after having burned their bridges behind them. Furthermore, they have defined their expatriation as a provisional and temporary state, resulting not from pursuit of the "American dream" but from escape from the "Cuban nightmare." They still think of a return to their homeland, and this conception has strengthened their sense of solidarity in exile. Indeed, coming into exile to the United States was a firmly established precedent in Cuba's political history. Numerous precursors—from José Martí, the founder of the nation, to five chiefs of state, including Batista and Castro themselves—were exiles in this country prior to their return to Cuba and ascent to historical significance or political power. In any case these dimensions form an ethnic consciousness for the expatriates, clustered around a "Cuban is beautiful" attitude and characterized by an ongoing reaffirmation of their cultural values and ethnic roots.

CONCLUSIONS

Despite their diversity, the almost one million Cuban expatriates in the United States share in a common experience of uprootedness, adaptation, and new growth. Accordingly, we have conceived of the prototypical experience of exile as a dialectic of loss and reconstruction, marked by a persistent conflict of loyalties and manifesting identifiable psychological patterns in the individual's response to the severe stress. Furthermore, Cuban expatriation has coincided with a period of rapid sociocultural change in the United States, thus exacerbating for the refugees the problem of adaptation to a radically new situation.

A complex of situational determinants has shaped the course of the exile process, and the resilience of Cuban families can be accounted for by a variety of factors that have mitigated the severe circumstances of expatriation. Among the most significant social determinants we have identified are the following: 1) characteristics of the exiles as a group, including a comparatively high level of education and occupational experience, familiarity with U.S. society, and ideological congruence with basic American values, 2) the creation of a network of relationships and activities within ethnic communities in the United States, the best example of which is the extraordinarily large colony in Miami, which in turn permits 3) the development and maintenance of a vigorous sense of collective identity and ethnic consciousness. Finally, we noted the significance of the reception accorded the refugees by the host country, which did not consign their fate to a fierce and arbitrary individual struggle, but rather organized it effectively through coordination of federal, state, county, municipal, and private agencies around the Cuban Refugee Center in Miami.

The arduous experience of exile has been traumatic for the Cuban expatriates, but it has nevertheless intensified life, tested and evoked their personal resources, and widened their horizons. For the United States as well as for the other nations in the world that face a swelling current of refugees, perhaps a moral can be drawn: the mass reception of refugees need not be a chaotic, counterproductive, or alienating experience—it can be an enriching, creative, and engaging opportunity to grow while learning a poignant lesson of universal history.

Prompt Publication Policy

The *Journal* would like to remind authors who are particularly interested in early publication (whether to establish priority of an idea, reveal innovative results of new research, or for other pressing reasons) of its prompt publication policy. Under this policy, short (maximum of six double-spaced pages) manuscripts will be considered for publication in the Brief Communications section of the first available issue. These manuscripts must still undergo expert scrutiny before being accepted, and two months must be allowed for the printing process. However, the time required for publication of these short articles can be lessened considerably.

Authors who would like to have their manuscripts considered under this policy should indicate this desire, as well as the reasons for it, when they submit their manuscripts.

Pseudohomosexuality in Feminist Students

BY ZIRA DEFRIES, M.D.

The author describes the influence of the feminist movement on the intellectual, social, and sexual behavior of feminist college students. The complex interrelationship between sexual political ideology and actual sexual behavior creates confusion and anxiety for some vulnerable students in their attempts to evolve a satisfactory sexual identity. A series of vignettes illustrates the struggle of such students, who initially expressed concern over actual or potential lesbianism and its connection to the movement, to resolve their conflicts concerning feminism and sexual preference.

WITHIN THE PAST decade there has been a rapid development of what has come to be known variously as the women's rights movement, feminism, and women's liberation. None of these terms is specific enough for a proper definition, but implicit in each are aspects connoting the need for political, social, interpersonal, sexual, and gender role change. Despite the amorphousness of the movement, certain pragmatic sociopolitical and ideological tenets are subsumed in its scope and its variegated forms.

A particularly suitable field in which to study various aspects of the feminist movement is a woman's college. Despite the fact that a college population is hardly a representative segment of women, it does permit a view of a group of women who are likely to be sensitive to social change, intellectually oriented, and introspective about themselves in relation to their immediate world. In addition, since college students are at a crucial stage in the development of a definitive sexual identity, they are particularly susceptible to a movement in which sexual values and mores are nuclear concepts and in which ideas implicit in the dogma readily lend themselves into translation into overt sexual behavior. For a limited number of vulnerable feminist students, the complex interrelationship between sexual political ideology and actual sexual behavior results in a syndrome here referred to as pseudohomosexuality. In this syndrome sexual behavior is strongly influenced by political ideology, and the resolution and consolidation of the adolescent phase of sexual identity development, with definitive sexual preference, are difficult and prolonged.

To provide historical perspective I will briefly review the development of the current-day feminist movement. I will also describe its evolution in a women's college of an urban university from groups that were loosely knit to units that became increasingly cohesive and characterized by varying degrees of political and sexual militancy. The different sexual behaviors manifested, i.e., homosexual, heterosexual, and bisexual, will be described within the context of the feminist students' struggle to evolve a satisfying sexual identity and preference.

ROOTS OF THE FEMINIST MOVEMENT

The feminist movement evolved from two main roots: 1) the National Organization for Women (NOW) formed in 1966, consisting initially of women who had been associated with the President's Commission on the Status of Women, and 2) young women who were involved in the civil rights and youth movements of the 1960s. The former, a more conservative group, has worked through the traditional channels of established power groups. The younger and more radical branch has produced more theoreticians and has shaped much of the ideological perspective that emphasizes personal change as a prelude to sociopolitical change. It has developed and spread techniques of consciousness raising as a means of demolishing or redefining stereotypic female concerns, including sex and interpersonal relationships, and has attempted to refashion not only women's ideas but their very identities. Many of the younger women see themselves as radical feminists in search of a "new woman identity" (1, 2). Lesbian feminism is part of the radical feminist ideology; its concern is with an alternative feminist lifestyle in which lesbianism is liberated from its conventional sexual context to a total emotional commitment toward women and a denial of the traditional reliance on men.

In this college the change in women's self-perception began to emerge openly during the 1968 student strikes when politically activist women complained about their oppressive roles in the student-occupied administration buildings. Demands for sexual equality became a unifying theme for the newly developing feminist movement. The first organized group to

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

appear on campus worked on women's issues exclusively, disassociating itself from the larger university group of political activists.

In 1972 the Women's Collective was formed, with the main purpose of raising female consciousness. In 1972 a few zealous feminists formed a group called Lesbian Activists; there was no opposition from the administration, although in 1963 two women had been expelled from the college for reported lesbianism. In 1973 a day-care project and a self-help clinic were opened, and regional conferences and workshops on women's roles (including lesbianism) were held. At the present time a wide range of ideologies exists on campus. The radical lesbian contingent constitutes a relatively small fraction of the overall feminist group, which includes nonradical heterosexual and bisexual students, many of whom consider a categorization of sexual preference irrelevant.

Feminist-oriented college students span an age period in which intense involvement in a cause can be considered an essential step in identity formation and a prelude to normal personality development (3). However, unmoderated or extreme ideological pronouncements that concentrate on selective aspects of interpersonal transactions may well be pathological (4).

For some students in the movement, the various expressions of sexual behavior advocated either implicitly or explicitly—in particular the encouragement of open expression of homosexuality—pose difficult problems. The educational and clinical approach to sexual functioning, including dissemination of information about such matters as masturbation and genital examination techniques, gives high visibility to female anatomy and physiology and helps to demystify sexual functioning. New approaches aimed at creating egalitarian concepts of male-female role relationships, both sexual and nonsexual, downgrade sex-typed behaviors and make unacceptable some ideals of masculinity and femininity that were formerly considered central to the development of a clear-cut sexual identification. Few standards remain for evaluating emotions and behavior in conventional terms. Considerable controversy over which behaviors should be totally discarded and which should be modified—and in what directions—still exists. An ideological stalemate is the inevitable result of seeking a more clear-cut definition of sexual modes of behavior. For some students this indeterminate state of knowledge provokes a great deal of anxiety and legitimizes further inquiry and exploration within a clinical framework.

CASE VIGNETTES

During the past 2½ years, nine feminist students with sexual identity and sex preference confusion were seen in the college psychiatric service. I have selected case material concerning three students as representative of the larger group. These students, in treatment for 2 or more years, were essentially obsessional personalities (and two exhibited hysterical traits). In keeping with the view of obsessionalism as a cognitive disorder, they demonstrate the way in which acceptance of ideology and dogma can be reassuring to the obsessional's doubt and ambivalence and how rejection of this same ideology produces depression and even suicidal thoughts (5).

In the initial interview, a concern over actual or potential lesbianism and its connection to the movement was invariably raised. Thereafter the themes included 1) vacillation between wanting total involvement in the movement to political but not personal involvement to no involvement, 2) alternate excitement and depression about lesbianism, and 3) castigation of men or infatuation with them. These students were preoccupied with the need to establish a unidirectional sexual preference as a means of achieving a satisfactory sexual identity. The problem, laconically conceptualized as "to be or not to be a lesbian," carries with it the expectation that when it is resolved, the feelings of dislocation created by this confusion and by fluctuating reactions to the movement would end.

Material abstracted from the initial interviews illustrates these students' concerns. For example, student 1 thought she was probably lesbian but was confused about whether or not to stand up for her lesbianism since she had a hard time pushing away men who were attracted to her. She wanted to be politically (but not personally) involved with gay people despite the fact that she was engaged in a sexual relationship with an "unliberated sexist female" student who, she said, exploited her feminism and rejected the "political me." She felt torn between politics and sex and longed to be free of the "distraction of politics."

Student 2 stated that as a result of her activity in the women's movement she had made too many major decisions, including the conclusion that she was definitely a lesbian and not even bisexual. She thought this lifestyle was too narrow and made no sense; she wondered why she had so defined herself. Before coming to college, she said, "It was all ideology and no acting out." At college the opportunity for being homosexual made her wish that men were around.

Student 3 claimed she had "gone overboard" with her ideas on feminism: "They are getting out of proportion." She had anticipated a sexual relationship with her closest woman friend and felt estranged when this young woman became attached to a man. Her activity in the women's collective affected her thinking and her friendships. "Movements are strange things—they get one going into ways that are incompatible with what actually goes on." She had been self-righteous about the movement but now wished she could be less defensive and more moderate. She stated: "Movement ideas have been given more of a priority than they deserve."

Shifts between vigorous espousal and rejection of the movement, accompanied by acceptance and rejection of lesbianism, occurred in rapid succession early in treatment and continued, although with decreasing

vehemence, as sexual relationships and ideological concerns were explored in greater detail. Sex was often perceived as the source of evil, and a moratorium was intermittently declared. A retreat to a purely political, asexual position was experienced as a momentary relief from the pressure of having to choose a one-way direction in the homo/heterosexual see-saw. Shifts of acted-out sexual behavior were commonly accompanied by depression and less often by euphoria.

Verbatim examples illustrate these dilemmas and the attempts to resolve them. Student 1 said, "When I became interested in the feminist movement I thought I had to be a lesbian and I was frightened. The more I read, the easier it became to equate lesbianism and feminism. Unless you take a belligerent stand of hating men you fear the old conditioning pressure to be heterosexual will win out." However, after declaring her lesbianism she became involved in a relationship with a man. "I realized how rigidly ideological I had been by saying I couldn't sleep with a man—that was bullshit. I feel trapped and discouraged by politics but I've been programmed to be political; the first day I came here I joined the women's collective and I haven't had a break since."

After a brief period of heterosexuality her feminism reasserted itself, and she literally cried for her lost lesbianism:

> All the strong feminist dreams and strength I felt from my lesbian identity are being crushed. Being a lesbian feminist has been my way of avoiding facing the fact that I can be heterosexual when I am with a man and that my identity is defined by the outside person. It is so confusing to relate to men and women at the same time. I don't have a fixed sense of myself. In the absence of the feminist movement, with its support in being gay, I could not have been a lesbian. On the other hand it is possible that if I had not had the crusade, I might have been more actively lesbian. The most involved feminists are lesbians. Total commitment is necessary. If you become active in feminism and believe in changing society, you question all the values of that society. If you are an intelligent female and can acknowledge sex feelings toward women it becomes impossible to be exclusively heterosexual.

The supreme irony occurred when a man asked her during intercourse if she was a lesbian.

Student 2 had had only heterosexual relationships until she came to college:

> Friendships with women do not require sex, yet relationships with females hover around sex. The things I think about feminism are related to the way I feel about my father; feminism gives me a right to villainize him. For me it is a personal dialectic, but I wonder how much social pressure makes people act in a certain way. I never used to feel secure unless I had a guy around. Now I refuse to be defined by a man's perceptions and I am paranoid about my life being guided by a man.

These feelings led to a dissolution of the sexual relationship she was having with a man:

> I feel alienated by men and am more satisfied emotionally by women, but I wonder how much my feminism is determined by personal feelings. The ideology of feminism is very personal; in most cases it is more than just a political thing. I wonder which way I will go sexually. My friends and I believe a sexual relationship comes out of sharing a close friendship and a similar ideology, but I am too interested in men to be a lesbian forever. Historically there has never been a better opportunity to experiment.

After this seeming complacency, however, she began to feel torn apart: "learning to trust men is not mutually exclusive with having close women friends. I don't know where my identity is at. I don't know what is going to happen to my feminism. I don't know where to put women." She became progressively more anxious about her sexual identity: "I must resolve my personal and ideological feelings so I can gain a sense of direction in life."

Student 3 initially felt that the only place she could find her identity was in the movement: "My identity is threatened by men and heterosexuality." However, she soon felt confused and frightened by men and fearful of women. Although she had been a prime mover of the feminist organization, she could no longer stand it: "The lesbian bar scene is a meat market—self-degrading and masochistic. I just want to be a political lesbian." After a brief affair with a man, she said, "I can no longer find consolation in the movement—it turns me off." This rejection of the movement led to a loss of her sense of self. "Politics used to be my whole self—now I can't relate to them."

She felt she was changing too fast and too drastically:

> It used to be everything was a woman—it was such a strong identity—now I have to learn to see things more realistically. I am adopting a new ideology. Sexuality is not the only thing we live for. I don't know what my sexuality is. I call myself a lesbian; I am a lesbian. I have a beautiful relationship with men—it is a definite conflict—in no time I'll be depressed again.

Instead, she threw herself into an intensive lesbian relationship. "It is great to be a lesbian—with women I am the real me." Even though she was not sure she could swing back to being a political lesbian feminist, she said, "I have the vibes back of my self-identity—feminist ideology has become my life." Not much later she began to feel suicidal as the pressure for a single direction of her sexual orientation became overwhelming: "I want to liberate lesbians from sex—to be a lesbian is to be a feminist—lesbianism is feminism, not just sex." Finally, she felt she could no longer compromise between the personal and political: "It splits my life into separate camps. I have become more certain of my own self and personality and sex preference; I am securely lesbian and have come to grips with this rare species, man." Having thus opted for lesbianism she rejected the movement: "I always believed the personal and the political cannot go together."

DISCUSSION

Undoubtedly family background and early developmental factors predisposed these conflicted students to (at the very least) "tilt" toward homosexuality. In adolescence they displayed strong intellectual and academic interests. Their perception of personal problems in a political context made them appear to have a broader intellectual scope than the more typical apolitical student. Although they often seemed emotionally childlike, they were impressively mature in their dedication to work in and out of the movement as well as in therapy.

Any attempt to predict the eventual outcome of the direction of sex preference of the nine students must remain tentative at this time. For the present, two of the three students still in therapy are tending toward a heterosexual adjustment, and the other appears to be predominantly homosexual. Of the remaining six, three developed a distinctly heterosexual preference, two a less clear but predominantly heterosexual adjustment, and one made what appeared to be a comfortable homosexual resolution.

The term "pseudohomosexuality" as applied to this group is reserved for that period during which ideology and manifest sexual behavior are inextricably mixed and sexual identity so confused that a unidirectional or at least a primary preference is not possible. At the same time a definitive sex preference is considered the means to providing a consistent, well-ordered world view through which feelings of confusion in regard to sexual identity can be resolved. During the period of most acute conflict, anxiety and depression are prominent symptoms. The problem is resolved when interlocking ideological and sexual identity and preference components are separated from one another so that more genuine sexual proclivities can be determined.

Feminist students who use the movement as an attempt to consolidate sexual identity do so for a variety of reasons, including coming to grips with sexual fears, postponing separation from parental ties (in these cases peer group ideology is substituted for family ideology), acting out of hostility toward males, and as an antidote to isolation and loneliness. In the course of therapy, movement concerns abate, militance decreases, and sexual behavior is no longer counterposed uncritically against ideology; thus the need for alternate homosexual and heterosexual acting out is curtailed. The exploration and reexamination of motives continue until either the sexual dilemma is resolved completely or there is an easier acceptance of a still wavering preference. When the young woman becomes an adolescent with a sexual problem rather than an ideologue, the anxiety associated with the movement markedly decreases. No longer does the movement serve as a cognitive and affective organizing focus around which sexual behavior pivots. By this process feminist ideology, formerly considered the essence of a self-identity around which a world view can be structured, loses its value as a means for determining sex preference.

The complexity of personal, social, and sexual factors in feminist doctrine injects a new component into adolescent female sexual identity development and preference that is not readily explainable by existing theories. The inconclusiveness concerning the evidence on the etiology of the mechanisms involved requires study along what Freud considered the circuitous unresolved path of female sexual development (6). Significant modifications of Freud's views have been made by Horney, Jones, Rubenfine, Kestenberg, Barnet, and Sherfey (7). The concepts of gender differentiation and identity described by Money and Hampson (8) and Stoller (9) are crucial additions toward understanding these mechanisms. However, in spite of agreement by developmental theorists that "adolescence is a period of greatly increased and more specific sexual interest, the psychosexual mechanisms remain largely untested and the question of the acquisition of the direction of sexual preference remains an open question" (10).

In an extensive review of the literature on female homosexuality Kenyon (11) confirmed what appears to be true for the students described here—that homosexual behavior in the adolescent may be part of a crisis of identity and should not be looked on as a fixed sexual orientation. Saghir and Robins (12), in their comprehensive study of nonpatient female homosexuals, pointed to a distinctive feature of childhood and adolescent cross gender behavior, starting at a very early age, with developing psychological responses that seem to have been determined early in life. They also cite the important fact of adolescent turmoil and frequent homosexual involvement of basically heterosexual adolescents as part of a specific "situation." Money and Ehrhardt (13) pointed out that in our present state of knowledge, no hypothesis can predict with certainty when a normal individual will become erotically homosexual, bisexual, or heterosexual. In discussing the etiology of homosexuality, Cooper (14) expressed a similar inconclusiveness; he believes that despite a literature of encyclopedia proportions, myriad investigations, and ingenious theories, the importance of various psychological and other factors in the etiology remains undetermined, although the consensus "leaves no doubt that the basic homosexual drive is fashioned in childhood, or at the latest in adolescence." He believes that Bancroft's model (15), which attempts an integration of gender identity and sexual preference based on the principle of cognitive consistency theory is "an eminently sensible way of looking at etiological factors." Cooper (14) finally and cautiously predicted that the complexity of society may defeat investigative efforts at finding a cause.

Developmental theorists with biological, psychoanalytic, and psychosocial orientations will continue to make revisions and emendations of their theories about sexual identity, prodded in part by the feminists' efforts to consolidate existing assumptions of sexual behavior that are at variance with their ideology. The collision, at many points, of psychological theory and

feminist doctrine brings both into the mainstream of current research on many fronts. Both camps have profited from charge and countercharge, and each has had to critique its own doctrines and affirm, extend, or discard particular facets. What better way to plug theoretical lacunae than by continuing controversy in the interest of greater understanding of sexual behavior.

It Is Always the Woman Who Is Raped

BY DEENA METZGER, PH.D.

Rape is described as an act of power that is sanctioned by literature, myth, and culture. Rape is a dire experience for women because it implies total loss of self—the woman is a function, not a person. The victim experiences total emptiness and isolation from self and society. The author believes that an effective "treatment" for the rape victim is community. Women asserting themselves by speaking out about their experience validate themselves as persons.

RAPE IS AN aggressive act against women as woman. The rapist is educated to his behavior by his society, and rape is the extreme manifestation of approved activities in which one segment of society dominates another. Rape is a ritual of power.

There are at least two ways of knowing. One is intellectual and the other is experiential. With which voice shall I speak to you? After rape there is a terrible silence. Then, if one is fortunate, one begins to learn to speak again. Why is the silence so terrible and so profound? What is the meaning of the crime that has been acted out? Why are its effects so dire?

Rape is the most common of the violent crimes. As the incidence of rape increases and we focus our attention on understanding the rapist—learning almost nothing of the victims—we continue the social patterns that perpetuate the crime.

Literature, art, and myth are full of images of rapes that are approved, even canonized. We distinguish the crime on the street from the "Rape of the Sabine Women," yet the painting by Rubens is informed by the same values that produce the street crime. Rape is the assault of a man on a woman, but it is also the symbolic enactment of social and cultural attitudes. On one level, perhaps unconscious, it is a gross and extreme form of social regulation by which woman is brutally stripped of her humanity and confronted with her definition as a nonperson, a function.

These attitudes are not peculiar to the rapist. The rapist is not an eccentric but an extremist acting out the being and nonbeing scenario that is basic to American society. In this scenario, the rapist uses power to confront the egalitarian aspect of sexuality—community. That the act that physically and symbolically indicates communion should be so often distorted into combat is not ironic but tragic, undermining essential relationships. Rape asserts only combat, brutalizing the communal aspect of sexuality, destroying meaning, relationship, and person, creating a universe of emptiness and ontological terror. There is no distinction between the male social intent and the private female response. A woman who is raped understands her condition with metaphysical clarity.

Rape is mythically asserted, artistically glorified, historically condoned, and symbolically urged in the media and in advertising. Persephone is a classic example of the rape victim. Persephone has been promised by Zeus to Hades. Her primary definition is property. The earth opens, Hades carries her within, imprisoning her in hell; she is isolated. Her mother, Demeter, mourns her, leaves Olympia, and in her grief withholds spring. Neither Zeus nor Hades is condemned. Male power is glorified, while Demeter, condemned for withholding, is reluctantly placated. Persephone is returned; spring comes. However, Persephone, having eaten pomegranate seeds while in hell, must return to Hades every year. Thus Persephone is responsible for winter. The victim

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editor considers this material to constitute a comprehensive analysis of the topic.

bears the burden and guilt of the crime that has been perpetrated against her.

We can translate this myth into contemporary experience. A man commits a crime against a woman. The authorities ask her, "Why were you walking alone? What were you wearing? What did you say? Are you a virgin? Did you pull down the shades?" Three basic attitudes of power are involved here: 1) to be weak is a crime deserving punishment, 2) the weak are accomplices in the crimes against them, and 3) the victim has committed the crime.

The stories of Persephone, Leda, and Europa are early mythic tales that teach rape as a learned cultural activity. The rights of men over women, the attitude underlying all cases of rape, were translated later into the droit du seigneur, the "giving" of the bride in marriage, the rites and rights of the marriage bed. These social customs reinforced the idea of woman as property, to be entered and used for man's purposes: woman as function.

A function is not a person. Rape is one manifestation of society's intent to depersonalize woman. It separates the woman from her humanity. Reduced instantly from person to object, property, flesh, vessel, the woman is immediately separated from anyone or anything that can comfort her. The basic experience of rape is isolation. Humanity depends on community, and the effect of rape is to destroy simultaneously the sense of community and the sense of person. Demeter and Persephone are separated because there is no comfort Demeter can give. Persephone is alone and empty. After I was raped, I knew that women were vessels, shells that could be emptied, flesh and bone frames without centers or substances. Women were moons shining only with reflected light, dead planets.

Because women's assertion of self conflicts with social and cultural patterns and with role and biology, the loss, after achievement, is grave. Rape is the instant proof of unalterable conditions, the erosion of years of work. Contemporary feminism has only begun to change this condition. The very unique interest of women in autobiography is a sign of the difficulty women have with identity. Where men always have asked, "What is the meaning of my life?" women are beginning to simply ask, "Do I have a life?" The effect of rape is the same whether the victim is a young girl, virgin, mother, or old woman. Rape is a crime against the person, not against the hymen.

My experience and that of the women I know tells me there is no treatment for rape other than community. Therapy or consciousness raising can be helpful as long as no "cure" for a "condition" or "disease" is implied. Rape is loss. Like death, it is best treated with a period of mourning and grief. We should develop social ceremonies for rape, rituals, that, like funerals and wakes, would allow the mourners to recover the spirits that the rapist, like death, steals. The social community is the appropriate center for the restoration of spirit, but the rape victim is usually shamed into silence and or self-imposed isolation.

In some ways, rape is never erased. Years later, even the word "rape" or the shadow of a familiar face can cause unexplained pain. The raped woman often cannot bear to be touched. Isolation is her condition. Touched, she knows she cannot feel; touched, she remains untouched. She is incarcerated in Hades. Her mother is outside and cannot hear her.

After I was raped, I had intercourse with my husband as a ritual gesture. (I had learned as a child to get back on my bike after falling, lest I never mount again.) Intercourse was easy. It didn't matter. I was an abandoned house. Vacated. Anyone or anything could enter.

Later I went through the ritual of talking to people. It always seemed as if I were talking through glass or underwater. I could never tell my mother; she couldn't bear the pain. Others, it seemed to me, drew away. I could not bear to be alone, but in company I felt abandoned, estranged. For months I looked to my husband for comfort he could or would not give. A year later, we began a divorce.

I felt endangered everywhere. Every noise startled me. Every leaf was camouflage for an assassin. For months a friend of mine described searching the faces on the street as if to ask, "Are you the one?"

Revenge became an obsession. My husband was a party to this; vengeance would relieve his feeling of impotence. We spent days searching the streets in a mythic ritual. He was looking for power. I was looking for self. If a crime had been committed, then perhaps there had been a victim and a victim is a person: perhaps I would find myself.

Rape is usually the assault by the stranger, the unknown asserting his perceived socially, culturally, politically, and God-given rights. In earlier times rape was more frequently enacted by familiars. The woman who was shared, given, offered, dedicated was in effect raped; to be entered without permission, invitation, or desire is to be raped. Today most rapes are forced entrance by a stranger. The stranger is anyone. Simply a hand emerging from the shadows. Being anyone, the rapist is everyone. He asserts that the woman does not belong to herself. She is there for his use, his pleasure. She is nothing in herself.

The rapist acts for the society, concretizing certain ideas through his behavior. He is often marginally integrated into the society, and rape is the way he affiliates himself, if not through the act, then through the attitudes. Through rape he asserts power and possession in a common violent and spontaneous action. By choosing to assert himself against woman and her body, he—like church, state, schools, advertisers, and the media—is simply asserting certain rights and prerogatives over woman, using her for his own purposes. He is translating cultural thoughts into action.

The rapist is any man against any woman. Some form of anonymity is essential. He acts against the woman who happens to walk down the street, happens to be stranded, happens to be alone. It is an act not against someone but against anyone. Chance is an es-

sential element. It reinforces the nonperson status of the victim, who is attacked at the moment of her nonbeing, in the shadows, alone, in silence, nameless; the rapist forces the identity of nonperson indelibly upon her. Whoever she had previously assumed herself to be, after the rape she is nothing: a body, a thing.

Yet rape is an assault on one's most private being. At her core, woman has a deep biological sense of herself, created through the cycles of blood and ovulation, through the pattern of puberty, menstruation, pregnancy, lactation, and menopause. This identity is enhanced by the cultural and symbolic values that the woman's body represents. It is this essence that is also violated: what she is and what she means. Finally, rape is a crime that gives the criminal pleasure. Not only is the victim possessed as by a demon, but she hears the demon laughing. She is used against herself. The groan of pleasure makes her feel despicable. Even before she is accused by police, parents, physicians, interrogators, she experiences herself as complicitor. Self-hate reinforces her personlessness.

Perhaps for these reasons, there are almost no stories of rape written by women. Leda is assaulted by a "feathered glory." A magnificent bull kidnaps Europa. Daphne, pursued by Apollo, becomes a laurel, but Apollo is not deformed. Woman is one of the expected spoils of war. Cassandra is not the only one who speaks and cannot be heard; there have been millions.

Because rape is an act of power that male society will not undermine, the woman is defiled. Perhaps less consistently than at other times, the victim is isolated or isolates herself; she enters a psychic quarantine as if she were contaminated, diseased, scarred. Although today women do not automatically lose their social and economic value through rape, they are devalued through accusations of seduction. The woman is suspect while the man is protected. Society asserts he is ill, marginal, or falsely accused. Men protect his rights and worry that the accusation may be false or the evidence contrived. The rapist is protected because he is themselves. The issue is always power. Rape, like the immaculate conception, becomes an act without an actor—the immaculate defilement.

The nonperson status of women is maintained in various ways, all of which seem to focus on sexuality. Symbolically, woman is the door, the opening, the entrance that must be sealed, protected. In one sense, according to Octavio Paz, woman is the essential violated one; she is the wound, the entered, *La Malinche*, *La Chingada*.[1] Her condition is one of violation, and it is against identification with such openness that man arms and armors himself. When man himself is entered and violated he is, according to Jean Genet, used as a woman, womanized, degraded.

Yet society simultaneously asserts that woman is the not-yet-entered, the innocent. The virgin is the unknown. To have intercourse is to know and be known. Sexuality is therefore knowledge, and woman is often insulated from this knowledge. That is part of the pattern of power and powerlessness, of being and nonbeing. To be without knowledge is to be nothing. For we are what we know. Woman at her best (as virgin) is thus nothing. Traditional heroines or women of power are grandmothers beyond sexuality, like Golda Meier, or virgins, like Mary, Joan of Arc, Elizabeth the Virgin Queen. The combined image of power and knowledge (sexuality) is terrifying: ogress, witch, Medusa, Clytemnestra, Medea—something to be destroyed.

The rapist acts against the societal injunction to protect the innocence of woman. He acts against the protection of woman, he denies the fortress of the private house. In so doing, he acts on the myth that for woman one error is fatal. Men, like the prodigal son, are capable of change, growth, learning. Women, for whom definition is finite, are confined within a single fall. Therefore the rapist has absolute power; he can destroy identity with a single act.

The raped young woman goes from nonbeing to Nonbeing—to not being at all. Rape is the act by which woman is known without knowing anything herself, the means by which knowledge and therefore presence is bypassed and nonbeing (innocence), which was tentative or temporary, becomes permanent. Raped, the woman becomes known, manifest, without gaining the identity that comes from knowledge. The only knowledge she gains is the knowledge of her lack of self.

With the exception of a few remarkable and brave women writers, including Doris Lessing, Simon de Beauvoir, Anaïs Nin, Kate Millet, and Colette, contemporary and historic literature (which reflects and creates social values and attitudes) asserts the nonbeing of women. From D. H. Lawrence's *Plumed Serpent* and *The Man Who Died Twice*, to Henry Miller's *Tropic of Cancer*, Norman Mailer's *American Dream*, and Erica Jong's *Fear of Flying*, nonbeing is the definitive condition of woman. And rape, which the film critic Arthur Knight recognizes as a "film cliché," is the act that confirms this nonbeing.

The literary, mythic, and historic attitudes toward rape are still with us. The charge against Joan Little for the murder of the rapist jailer who assaulted her is the classic case of the victim accused of the crime. It is as if simple defenselessness, isolation of woman in itself, invites attack. The circle is complete. Men isolate women and then accuse that isolation. Rape is socially seen as response rather than provocation—it is the desperate male response to a powerlessness that is confirmed for him by the spectre of female identity. Similarly, when Inez Garcia acted as a person against her attacker, she was the one charged. Worse than the image of an attacked woman is an image of a woman

[1] *La Malinche* refers to the mistress of Cortez, the Indian woman through whom the invasion occurred: "The Mexican people have not forgiven *La Malinche* for her betrayal. She embodies the open, the *chingado*, to our closed, stoic, impassive Indians. . . ." "The *Chingada* is the Mother forcibly opened, violated, or deceived. . . . This passivity, open to the outside world, causes her to lose her identity . . . she is no one; she disappears into nothingness; she is Nothingness. And yet she is the cruel incarnation of the feminine condition" (1).

counterattacking. Here, the contradiction of nonbeing creates panic.

In a society such as ours, where the fantasy of power is a constant stimulus and Superman, John Wayne, James Bond, and Kissinger are cultural heroes, while powerlessness and alienation are the reality, it is inevitable that rape occurs frequently. Males denied power in their daily lives find means to act as if they had it. Women are the obvious victims because male society still defines them as powerless, functional nonpersons. Providing men with the feeling of power has been considered to be one of woman's duties.

In 1968 I was raped at gunpoint. Later, lying naked on the floor, I could only whisper over and over again, "One doesn't treat people like this." I had had only a momentary glimpse of the rapist, a stranger. From my brief description, a police artist drew a face identical to a photo I later identified in police records. This man, who was on parole, had been incarcerated for rape. His parole officer called him in for questioning but concluded on the basis of an alibi that he had been too far from the scene of the crime.

The first fictional account I wrote of the rape (in an unpublished novel titled "Flying With a Rock") was couched in fantasy. I described the rape of a madwoman. I was still maddened by the assault and could only develop a character who had lost all sense of herself. Four years later I wrote a more accurate version, which describes a woman both overpowered and divested of her power (2). Her last words are "I cannot." She is emptied out. I decided to make this public in order to break some of the silence and isolation which reinforces the personlessness of women. The private voice in the public sphere confirms our common experience through which we begin to assert ourselves. Unlike my character, now, I can.

The Rape Victim: Psychodynamic Considerations

BY MALKAH T. NOTMAN, M.D., AND CAROL C. NADELSON, M.D.

Rape challenges a woman's ability to maintain her defenses and thus arouses feelings of guilt, anxiety, and inadequacy. Women's individual responses are determined by life stage considerations as well as their defensive structures: concerns about separation-individuation may be aroused in the young woman; a divorced or separated woman may find her credibility questioned; older women's fears of sexual inadequacy may be compounded. In counseling, the victim's previous adjustment should be assessed, she should be given support and reassurance, and specific considerations related to her life circumstances should be acknowledged and dealt with.

The authors are with Beth Israel Hospital, 330 Brookline Ave., Boston, Mass. 02215, where Dr. Notman is Psychiatrist and Dr. Nadelson is Associate Psychiatrist and Director, Medical Student Education. They are also with Harvard Medical School, Boston, Mass., where Dr. Notman is Assistant Clinical Professor of Psychiatry and Dr. Nadelson is Assistant Professor of Psychiatry.

THE EXPERIENCES that we call rape range from surprise attacks with threats of death or multilation to insistence on sexual intercourse in a social encounter where sexual contact is unexpected or not agreed upon. Consent is crucial to the definition of rape. The importance of mutual consent is often overlooked and misinterpreted; many people assume that certain social communications imply willingness for a sexual relationship. Although men, women, and children are raped, the majority of rape victims are women; this paper will focus on understanding rape as a psychological stress for the woman victim.

Burgess and Holmstrom (1) divided the rape victims they studied into three groups: 1) victims of forcible completed or attempted rape, 2) victims who were "accessories" because of inability to consent, and 3) victims of sexually stressful situations where the encounter went beyond the woman's expectations and ability to exercise control. Despite the different circumstances, the intrapsychic experiences of rape victims in all categories have much in common.

The rape victim usually has had an overwhelmingly frightening experience in which she fears for her life and pays for her freedom in the sexual act. Generally, this experience heightens a woman's sense of helplessness, intensifies conflicts about dependence and independence, and generates self-criticism and guilt that devalue her as a person and interfere with trusting relationships, particularly with men. Other important consequences of the situation are difficulty handling anger and aggression and persistent feelings of vulnerability. Each rape victim responds to and integrates the experience differently depending on her age, life situation, the circumstances of the rape, her specific personality style, and the responses of those from whom she seeks support.

RAPE AS A STRESS

Rape can be viewed as a crisis situation in which a traumatic external event breaks the balance between internal ego adaptation and the environment. Since it is an interaction between an extreme environmental stimulus and the adaptive capacity of the victim, rape is similar to other situations described in the literature on stress, including community disasters (2, 3), war (4–7), surgical procedures (8, 9), etc. The unexpectedness of the catastrophe and the variability of victims' resources for coping with an experience that may be viewed as life-threatening are critical factors in rape, as in other crisis situations.

Although there are cultural and personality style differences, descriptions of stress reactions generally define four stages, which vary in intensity and duration (10). These responses, listed below, are also found in rape victims.

1. Anticipatory or threat phase. In this stage, anxiety facilitates perception of potentially dangerous situations so that they can be avoided. Most people protect themselves with a combination of defenses that maintain an illusion of invulnerability, with enough reality perception to allow them to protect themselves from real danger. When a potential stress is planned (i.e., elective surgery), an individual can protect his/her ego integrity by strengthening those defenses which will ward off feelings of helplessness.

2. Impact phase. Varying degrees of disintegration may occur in a previously well-adapted person during this second phase, depending on the degree of trauma and the adaptive capacity of the individual. There may be major physiological reactions, including vasomotor and sensorial shifts. Tyhurst (2) reported on the extremes of fire and flood victims' reactions, which ranged from "cool and collected" to "inappropriate" responses, with "states of confusion, paralyzing anxiety, inability to move out of bed, hysterical crying, or screaming." The majority of these victims showed variable but less extreme responses—they were "stunned and bewildered" and demonstrated restricted attention and other fear responses, such as automatic or stereotypical behavior. This picture is also seen in rape victims.

3. Posttraumatic or "recoil" phase. Emotional expression, self-awareness, memory, and behavioral control are gradually regained in the recoil phase. However, perspective may continue to be limited and dependency feelings are increased. The individual perceives adaptive and maladaptive responses in him/herself and may question his/her reactions. A positive or negative view of one's ability to cope may affect the course of resolution of the trauma and future capacity to respond to stress, and self-esteem may be enhanced or damaged.

Group support during this phase enables the victim to feel less isolated and helpless. Obviously, the rape victim, who is usually alone during the attack, can only hope for support later. Women are often disappointed by the failure of family, friends, and the community to validate their experience.

Janis (9), in his study of surgical trauma patients, noted that any threat that cannot be influenced by the individual's own behavior may be unconsciously perceived in the same way as were childhood threats of parental punishment for bad behavior. This results in attempts to control anger and aggression in order to avoid provoking "punishment." The absence of overt anger is also a very prominent finding in rape victims.

4. Posttraumatic reconstitution phase. A process occurs during this phase that may alter future life adjustment. The loss of self-reassuring mechanisms that had fostered a sense of invulnerability may result in a decrease in self-esteem. The victim then blames him/herself for lack of perception or attention to danger. Kardiner and Spiegel (11) studied war stress and stated, "As soon as fear is directed inward in the form of questioning the individual resources to cope with external danger, or toward the group in the form of questioning its ability to be a protective extension of the individual, then a new and more serious danger situation is created." Maladaptive responses have been reported in the war neuroses of World War II (12), in which the individual develops mechanisms that are protective against further exposure to trauma but are psychologically costly and may involve loss of pride and self-esteem (13).

The rape trauma syndrome described by Burgess and Holmstrom (1) can be considered a form of stress reaction that can lead to traumatic neurosis. They reported an acute disorganizational phase with behavioral, somatic, and psychological manifestations and a long-term reorganizational phase with variable components depending on the ego strength, social networks, and specific experiences of the victim. They focused on the violent life-threatening aspects of the crime. Two types of response they noted are: "the expressed style," in which the victim is emotional and visibly upset, and the "controlled style," in which denial and reaction-formation seem to be the most prominent defenses. They also described feelings of shock and disbelief in many victims and the prevalence of

guilt and self-blame in the initial phase. The reconstitution phase varies considerably with each individual; however, the patterns of response appear to be similar to those reported in the other types of stress reactions we have discussed.

THE DYNAMICS OF THE RESPONSE TO RAPE

The important considerations in understanding the dynamics of women's responses to rape are 1) affects, 2) unconscious fantasies, and 3) adaptive and defensive ego styles.

Anger

A striking phenomenon in rape victims is the initial display of fear, anxiety, guilt, and shame—but little direct anger. There are several probable reasons for this.

1. Since rape may evoke memories of childhood threats of punishment for misdeeds (9), the victim may feel that she is being punished or is in some way responsible. Her anger may be repressed and experienced as guilt and shame, despite her concomitant feelings of helplessness and vulnerability. Most of the angry feelings appear later in recurrent nightmares, explosive outbursts, and displacement of anger as the woman attempts to master the assault.
2. Expression of aggression in women has been highly conflictual because of cultural restrictions and expectations of passivity and greater compliance for women. Women have often tended toward a masochistic orientation, in which anger is transformed into culturally supported patterns of self-blame. Identification with the aggressor, a mechanism that serves as an attempt to gain mastery, may also make it difficult to acknowledge anger toward the rapist.
3. The socially reinforced suppression of aggression in women has a possible adaptive function, since women are usually smaller and physically weaker than men. Therefore, not responding with a counterattack may prove beneficial. This is an important consideration in understanding the concept of consent. In the past, legal expectations included evidence of force or a struggle in order to establish rape. Current laws accept threat of force as sufficient, recognizing that a woman may submit in fear rather than risk fighting and being overcome.

Guilt and Shame

Despite the varying circumstances of rape and the different degrees of violence, surprise, and degradation involved, guilt and shame are virtually universal. The tendency to blame the victim, thereby assigning responsibility to her, fosters guilt and prevents her from adequately working through the crisis. It is common for a rape victim to feel that she should have handled the situation differently, regardless of the appropriateness of her actual response. Concerns about the amount of activity or passivity that might have prevented the attack or the rape are frequent. The assumption is that the woman should or could have handled the situation better, that her unconscious wishes perhaps prevented more appropriate assessment and more adaptive behavior.

The guilt of the victim is further increased by focusing on the sexual rather than the violent aspect of the experience. Although aggression is most prominent in the victim's perception, society regards rape as sexual. Since long-standing sexual taboos still persist for many people, even an unwilling participant in a sexual act is accused and depreciated. The popular adage that advises the woman who cannot avoid rape to "relax and enjoy it" misconstrues the attack as a sexual experience. In reality, the rape experience is depersonalizing and dehumanizing. The woman is often a faceless object for the rapist's expression of hostility, and the victim feels degraded and used. Furthermore, since women are expected to exert impulse control in sexual encounters, the rape victim's sense of failure in setting limits, impossible though this may have been, contributes to her guilt.

Unconscious Fantasies

The question of unconscious wishes translated into provocation of a rape must be seriously considered. While undoubtedly there are unconscious fantasies in which rape plays a part, and some women do have fantasies in which submission to a stronger man may be linked with forbidden oedipal wishes, on the conscious level the women knows she is submitting because any other behavior would result in real danger to her life. However, this is not so clearly differentiated in the unconscious. The universality of rape fantasies certainly does not make every woman a willing victim—or every man a rapist. The unconscious fantasy does not picture the actual violence of the experience.

An individual's defensive organization usually protects him/her from acting out such fantasies. However, if the defensive barrier breaks down and unconscious destructive, aggressive, or masochistic wishes gain expression, anxiety over the loss of control combines with guilt regarding the impulses. Rape involves an overwhelming confrontation with another individual's sadism and aggression and one's own vulnerability. This challenges the woman's confidence in her ability to maintain her defenses and controls.

Many women feel some ambivalence toward men as a result of past developmental experiences. Women expect men to be their protectors and providers, as well as relating to them sexually. Men may also be seen as potential aggressors and exploiters, and the experience of rape confronts the woman with this violent potential. The betrayal by the supposed protector who turns aggressor has a profound effect. Almost all rape victims say they trust men less after the rape. All men may be suspect, and all are potentially on trial. Uncertainty about one's ability to control the environment reverberates with concerns about the ability to control and care for oneself.

Men's Responses to Rape

It is important to consider the responses of men who participate in discussions about rape. They often feel indignation and sometimes identify with both the victim and aggressor. They may feel their masculinity is violated by both the attack on a woman who is felt to "belong" to them and by their own helplessness deriving in part from early feminine identification as well as from their actual failure to have prevented the attack. This may be particularly threatening to men who need to reject any latent feminine components of their own personalities and may lead to a defensive identification with the rapist in an attempt to escape the anxiety of their own sense of vulnerability. Some men have difficulty coping with the impulse for revenge, which would reestablish their sense of control and the ability to protect "their" women.

A man whose daughter, girlfriend, or wife has been raped may react by becoming overprotective, partly as a result of his sense of guilt for not having been protective enough. However, it may also evolve as a defensive means of handling his anger at the attacker of "his" woman and at the woman for having allowed herself to get in this position. A complex series of feelings about his own sexual impulses may be evoked, and a man may find himself unable to be supportive or helpful to the woman after the rape, despite a previously close relationship. He may have difficulty with his own rape fantasies, his concerns about "used merchandise," and even the breakthrough of homosexual impulses. He may withdraw from the woman as a result of this anxiety. The woman who is deprived of support from a man who is important to her is particularly vulnerable to adverse reactions after a rape. The man may be unaware that he is not supportive, since denial operates to minimize the experience so it can be forgotten.

LIFE STAGE CONSIDERATIONS

It is difficult for anyone to predict how he/she will actually behave in a crisis. In the state of panic evoked during a rape, most women think about how to behave to avoid being physically injured or killed. Some talk, some resist, and others become passive, depending on their assessment of what is going on and their past styles of managing stress (14). There are, however, some specific issues related to age and life stage.

The Young Single Woman

The single woman between the ages of 17 and 24 is the most frequently reported rape victim. She is vulnerable often by virtue of being alone and inexperienced. Her relations with men have frequently been limited to the trusted, caring figures of her childhood or the young men she dated in high school. She enters the adult world with little sophistication in some of the nuances of human interaction, and she may easily become involved in an unwelcome sexual encounter. In this age group, the frequency with which rape victims report prior knowledge of the rapist is striking, and this is often the reason for a victim's refusal to prosecute. A young woman may have been raped by a date, an old friend, or even an ex-husband, and she oftens reproaches herself because she should have "known better" or been more active in preventing the rape.

As was discussed earlier, feelings of shame and guilt are prevalent regardless of the circumstances of the rape; coupled with the victim's sense of vulnerability, these feelings color the victim's future relationships with men. This is especially true for the very young woman who may have had her first sexual experience in the context of violence and degradation.

The experience of rape may revive concerns about separation and independence. A young woman's sense of adequacy is challenged when she asks, "Can I really take care of myself?" Parents, friends, and relatives often respond with an offer to involve themselves in taking care of her again. Although the offers may be supportive and reassuring, they may also foster regression and prevent mastery of the stress and conflict evoked by the experience.

Problems for the younger rape victim also affect her perception of and tolerance for gynecological examination. She may have suffered physical trauma, she is susceptible to venereal disease, and she may become pregnant. An examination is indicated, but it may be perceived, especially by an inexperienced or severely traumatized woman, as another rape. She is concerned about the intactness and integrity of her body and wants reassurance. However, she may have difficulty dealing with the necessary procedures if they stimulate memories of the original rape experience.

The Divorced or Separated Woman

The divorced or separated woman is in a particularly difficult position because she is more likely to be blamed and have her credibility questioned. Her lifestyle, morality, and character are frequently questioned. Her apparent sexual availability makes her seem more approachable sexually. She may experience the rape as a confirmation of her feelings of inadequacy, and she is especially likely to feel enormous guilt that can lead to failure to obtain aid or to report the crime. Her ability to function independently is challenged. If she has children, she may worry about her ability to protect and care for them, and others will probably raise questions about her adequacy as a mother. The woman with children must deal with the problem of what, how, and when to tell them about the rape. If the event is known in the community, its implications for her and her children may be difficult to manage.

The Middle-Aged Woman

For the middle-aged married woman, issues of her ability to have control and her concerns about independence are particularly important. She is often in a peri-

od of critical reassessment of her life role, particularly in the face of changed relationships to her grown-up children. Husbands in their own midlife crises are often less responsive and supportive to their wives' sexual and emotional needs.

There is a common misconception that a woman, married or single, who is past her most sexually active period has less to lose than a younger woman. One cannot quantify the self-devaluation, feelings of worthlessness, and shame in any woman—especially a woman who may already be concerned about her sexual adequacy.

ATTITUDES OF PROFESSIONALS

Until recently, many psychiatrists felt that rape was not a psychiatric issue and that psychiatrists had little to offer the rape victim. They often shared the view that the victim "asked for it," and she was seen as acting out her unconscious fantasies and therefore was not a "true victim." Thus the woman who had been raped did not receive the empathy and understanding usually extended to people in a crisis. There is also the common belief that many accusations of rape are false. We have not found this to be true in the majority of cases seen at the Rape Crisis Intervention Program at Beth Israel Hospital, nor have others in this field with whom we have spoken.

Professionals have shared the image of the rape victim as a young, sexually attractive woman who in some way exposes herself to an avoidable danger or uses the accusation of rape to save herself from criticism. This view of rape implies that it happens only to marginal people, who collude in some way, and this idea fulfills several functions. It protects the individual who accepts the view from anxiety about his/her feelings of vulnerability. It is also another way to deny that rape occurs and that its incidence is increasing. This defensive position is further expressed by the focus on the sexual aspect of rape. If it is sexual, then one can think that the victim and the rapist were both seeking sexual gratification. The professional is thus protected from any sense of guilt or responsibility.

In our own experience in the development of a rape crisis program at Beth Israel, we saw a change of attitudes in participating professionals. An increase in interest results in recognition of the crisis nature of the experience and increased dignity for the individual victim.

CONSEQUENCES OF RAPE

Attention to the long-term effects of rape is important. It is difficult to predict all the long-term needs of the rape victim, since the working out of the trauma proceeds in many different ways. The feelings aroused may lead to behavior that seems out of character and would be puzzling if it were not for the rape. Some of the issues that reemerge in some women at a later time are 1) mistrust of men, with consequent avoidance or hesitation; 2) a variety of sexual disturbances; 3) phobic reactions to situations that are reminiscent of the rape; and 4) anxiety and depression, often precipitated by seemingly unrelated events that in some small details bring back the original trauma.

COUNSELING CONSIDERATIONS

Counseling of rape victims should involve an assessment of previous adjustment, including stress tolerance and adaptive resources. In addition, it is also important to learn whom in her environment the victim views as supportive and to attempt to involve these people if possible.

The woman in this situation needs support and reassurance about the way in which she handled the encounter and her efforts to cope afterward, even if she seems volatile, disorganized, or guilty. Negative countertransference feelings may be evoked if she displaces her anger onto those who are attempting to help, e.g., friends, doctors, or the police. It is important that she have the opportunity for constructive catharsis with a caring and empathic person. The counselor's patience may be tested by the victim's repetitive retelling of the story. The counselor may need to be available frequently for the more overtly upset rape victim. The more subdued victim may need to be encouraged to communicate and should be offered the opportunity for future counseling.

Each woman presents special considerations and requires the acknowledgment and support of the counselor in verbalizing and working through the complex problems she faces. The young woman needs help in confronting her family, her relationships with men, and her feelings about her sexuality; the woman with children must deal with her communication with them; and the older woman may have to face her sexual anxiety more openly.

Coping Behavior of the Rape Victim

BY ANN WOLBERT BURGESS, D.N.SC., AND LYNDA LYTLE HOLMSTROM, PH.D.

The coping behavior of rape victims can be analyzed in three distinct phases–the threat of attack, the attack itself, and the period immediately thereafter. The authors analyzed the reported coping behavior of 92 women diagnosed as having rape trauma. Most of the women used verbal, physical, or cognitive strategies when threatened, although 34 were physically or psychologically paralyzed. The actual rape prompted coping behaviors in all but 1 victim. Escaping the situation or the assailant is the primary task immediately after the attack. In counseling the rape victim, it is important to understand her individual style of coping, to be supportive of it, and to suggest alternatives for future stressful situations.

THE BEHAVIOR of people faced with critical life situations is receiving increased attention in the literature (1). The immediate efforts people use to deal with highly stressful situations are an important assessment point for clinicians who see patients in acute crisis. These coping behaviors may be viewed as problem-solving attempts an individual makes when facing demands that are highly relevant to his/her safety and that tax adaptive resources (2). Before describing the various coping strategies used by rape victims facing attack, it will be useful to review some coping strategies found in other types of crisis or stressful situations.

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Burgess is Associate Professor of Nursing and Dr. Holmstrom is Associate Professor of Sociology, Boston College, Chestnut Hill, Mass. 02167.

Researchers have focused on different aspects of the coping process. Extrasensory awareness of disaster situations was studied by Stevenson (3) in 19 people who survived the sinking of the Titanic. Glass (4) considered behavior over time in order to be able to view various phases of behavior separately. Most of the clinical studies have reported on the use of psychological mechanisms as part of the coping process: examples include denial in people with acute myocardial infarction (5), isolation of affect, denial, and regressive behavior in victims of concentration camps (6), denial, isolation of affect, and motor activity in parents of children with malignant disease (7), and emotional constriction, repression, suppression, denial, and delusion-hallucination formation in severely burned patients (8). Lazarus (9) took a behavioral approach and classified four important coping reaction patterns: 1) actions aimed at strengthening the individual's resources against harm, 2) avoidance, 3) attack, and 4) inaction.

There have been several recent studies of victim crisis situations involving major crimes, including forcible rape and situations in which victims have successfully interrupted or prevented attack (10–12). Giacenti and Tjaden (13) reported that out of 915 cases in the Denver area, 319 victims were able to interrupt the rape by active resistance, fleeing, physically fighting, crying aloud, verbal refusals, and outside intervention. In studying rape prevention, Brodsky (14) has focused primarily on verbal or vocal responses in the interpersonal prerape situation.

We saw a variety of ways to look at the coping behavior of rape victims in the literature. We drew on these studies and took a combination of areas to analyze, emphasizing the thoughts, feelings, and actions of rape victims as they related to specific time phases of the attack.

TABLE 1
Coping Behavior of 92 Rape Victims in Response to Threat of Attack

Description of Behavior	Number of Victims
Victims with strategies (N=58)*	
Cognitive assessment	18
Verbal tactics	57
Physical action	21
Victims without strategies (N=34)	
Physically paralyzed	22
Psychologically paralyzed	12

* Many victims had more than one strategy; therefore, the total numbers exceed 58.

METHOD

We interviewed all persons entering the Boston City Hospital Emergency Department over a one-year period with the chief complaint of having been raped. Subjects were interviewed at the hospital, usually within hours of the attack. The interview included a series of open-ended questions in which victims were asked how they felt and reacted to the circumstances prior to the attack, the attack itself, and the chain of events following the attack. Follow-up interviews were possible with 85% of the total sample of 146 victims and included further recounting of the details of the attack. Diagnostic categories were devised from the total sample, and a subsample of 92 women aged 17–73 diagnosed as having rape trauma (15) was used in this analysis of coping behavior before, during, and immediately following the attack.

BEFORE THE ATTACK: COPING BEHAVIOR IN A THREATENING SITUATION

Most of the victims perceived the rape as a life-threatening experience. The minority who did not so perceive it still saw the rape as an acutely stressful, frightening, and degrading experience. For almost all victims, this attack was something far out of the ordinary that seriously taxed their adaptive resources.

Early Awareness of Danger

Appraisal of the degree of danger, threat, or harm is a psychological process that intervenes between a stressful event and coping behavior. This early awareness may be cognitive, perceptual, or affective—often, the victim describes it as a "sixth sense" or a feeling of impending danger. The coping task during this phase is to react quickly to this warning.

Only 15 of the 92 women we interviewed spontaneously reported some cognitive or perceptual awareness of the potential danger they faced, and they were not totally clear about the nature of the danger—they just knew that something was wrong. Reports of this vague, obscurely formulated consciousness of danger varied. Victims said they saw a strange man and either thought he might do harm, wondered why the man had been hanging around all evening, remembered seeing the man before, looked at the car that pulled up, thought it strange the apartment light did not go on, or heard a noise in the kitchen and went to investigate.

Several victims described a subjective awareness alerting them to danger such as being scared when their boyfriend was pushed out of the car or feeling frightened when they realized what was happening.

Threat of Attack

The threat of attack is the point when the person realizes there is definite danger to his or her life—the coping task at this stage is to attempt to avoid or escape the situation. The person is aware something critical is going to happen but may not realize that rape is the imminent danger; for example, the person may instead fear robbery or aggravated assault.

Coping behavior was analyzed in terms of whether or not victims were able to react to the confrontation with danger. This ability to react often depended on the amount of time between the threat of attack and the attack, the type of attack, and the type of force or violence used.

A majority of victims used one or more strategies and a minority of victims were unable to use any strategies (see table 1).

Basic Strategies

Cognitive assessment. Victims may cope by mentally assessing the situation to determine possible alternatives, e.g., they may think about how they can get away from the assailant's grasp or escape from a car or room safely, or they may worry that the man will panic and hurt them and plan how to keep calm.

Verbal tactics. The majority of the coping strategies were verbal; they included talking one's way out of the situation ("I tried to engage them in conversation such as asking where they went to school and why they were doing this"), stalling for time ("I tried to talk to him; tried to get him to come for coffee at a restaurant down the street"), reasoning with the assailant by trying to change his mind ("I'm a married woman"; "I'm a virgin"), trying to gain sympathy from the assailant ("Look at the trouble you're causing me"; "What will I do?") using flattery ("You're an attractive man; surely you don't have to do this for sex"), bargaining with the assailant ("There's my TV, take it and go"), feigning illness ("I'm sick"), threatening the assailant ("My husband is due home"; "My kids are in the next room"; "A policemen lives in this building"), verbal aggression ("Get your hands off me"; "Don't touch me"; "What are you doing?"), changing the assailant's perception of the victim ("I talked to him like a mother."), joking and sarcasm (a woman awakes to see a man coming in her room saying, "I'm escaping from the police"; she says, "OK—I'll let you out the back door").

Physical action. Some victims took direct action aimed at preventing the attack by fleeing from the situ-

ation or fighting the assailant ("I tried to stab him with the broken glass"; "I tried to push him back out of the apartment").

Lack of Strategies

One-third of the victims were unable to use any strategy to avoid the attack. The victim might be physically paralyzed and totally overpowered by the assailant. For example, several victims were in their beds sleeping when the assailant gained access to their apartments and attacked them ("It was around 3 a.m. . . . I woke to feel someone jumping on me"). The victim might be walking down the street and suddenly grabbed by one or two assailants. The use of a weapon often paralyzed a person. The following example from a referral case illustrates early awareness of danger and physical paralysis: "The door buzzer rang . . . I was expecting friends and opened my door . . . saw three men with a paper in one's hand . . . I froze . . . paralyzed for a moment . . . something went through my head . . . shut the door but they pushed it back open . . . with the gun . . .." In some cases, the victim was totally stunned or surprised by the change in behavior of a man whom she knew as a friend, neighbor, or acquaintance, and said "He just grabbed me before I knew it."

Victims may be psychologically paralyzed either through their defensive structure ("When I realized what he was going to do I blanked out . . . tried not to be aware of what was going on") or because of their use of alcohol or drugs prior to the attack. Thoughts of death may paralyze a victim ("I thought he'd be the last person I'd see alive").

Multiple Strategies

Victims may try a number of strategies: 31 women had multiple strategies, 27 had one, and 34 had none. One woman who was successful in avoiding attack said, "First I tried to calm him down; tried to talk softly to him and said, 'OK, we be friends.' Then I said my brother was due home any time . . . I tried all I knew, verbal and physical . . . I screamed and fought . . .." The brother did come home and the assailant left without completing the rape.

Another victim who tried several strategies was not successful with three men who had forced her into a car as she waited for a bus after her evening classes at a local university. She tried verbal tactics ("My husband will be worried and probably call the police if I am not home"), but the assailants told her that such remarks would "get me dead." The victim then became silent. She later tried bargaining ("I offered them my money to let me go") and finally decided to comply ("I decided the only way was to play it their way").

In another case, one can see the coping behaviors of early awareness, an affective reaction of fear, cognitive assessment, and verbal tactics of joking: "I got a warning . . . saw two men at the end of my hall . . . got frightened . . . didn't know how they got there. They said they needed to use my phone. I tried to joke and said, 'Who you trying to call, Red China?' "

DURING THE ATTACK: COPING WITH THE RAPE

At the moment of the actual rape attack, it becomes clear to the victim that forced sexual attack is inescapable. The coping task during this phase is to survive the rape despite the many demands forced upon the victim, such as oral, vaginal, and anal penetration. She also may be forced to have conversation with the assailant. Victims coped with the actual rape in a variety of ways, as table 2 indicates.

Cognitive Strategies

Victims often cope by mentally focusing and directing their attention to some specific thought to keep their minds off the reality of the event and focus on their survival. Remaining calm was a strategy in which the victim specifically controlled herself mentally so as not to provoke additional violence. The victim might talk to herself, as in the following case:

> I kept thinking . . . keep cool. He said he'd kill me. He hit me, he choked me, he could kill me. I said to myself, 'You can handle anything; come on, you can do it.' I decided not to fight him . . . he was holding my neck so tight . . . I responded a little to him . . . that blew his mind that I acted as I did. It was very quick, thank God.

Memorizing details was a strategy that paid off later in some cases. One referred victim said, "I focused on their faces and thought to myself, 'I'll see you guys in court if I get out of this alive.' " She did. Another victim said, "I played detective . . . tried to observe everything, like the tatoo on his arm, remarks he made, route of travel of the car, license of the car."

Recalling advice people have given on the subject of rape is another strategy victims report: "I remember a conversation I had with my husband. He said if I was attacked not to resist if he wants sex. My husband said

the guy could kill me or the children . . . but sex wouldn't kill me." Another victim said, "I remember talking with people about rape and they always said not to resist . . . that a female could be killed, beaten, or mutilated. I didn't want that to happen."

Memories of previous violent situations provided some victims with alternatives ("I struggled a little . . . then remembered when I was 12 I fought a neighbor boy and got my nose broken"). Praying for help is a tactic to decrease stress and tension ("I wasn't listening to them but concentrating on praying that my friends who had keys to my apartment would come"). Concentrating on the assailant in terms of who he is and what has led to this attack is also a strategy ("I remember thinking that this person must have a home—must live somewhere . . . why would he do this on Mother's Day? . . . I thought of the irony of it . . .") Compliance is a strategy used to "speed it up . . . get it over with." To many victims, the attack seemed interminable.

Verbal Strategies

Victims combined verbal and affective responses by screaming and yelling. This tactic served both to relieve tension involuntarily and to deter the assailant from his full intent. This tactic brought police to the scene in several cases, which sometimes resulted in the assailant being apprehended during the attack.

Several victims believed that talking with the assailant during the attack helped them avoid additional violence. The assailant may demand to know how the victim is "enjoying" the rape. One victim handled the situation as follows: "He kept wanting to know if it felt good and I had to say yes to keep him happy . . . He said, 'I'm on drugs lady and I need money . . . fuck me good or I'll kill you.' He needed to be reassured."

If the attack continues over a period of time, the victim may try verbal tactics to calm the assailant and thus avoid further demands ("I talked to calm him down . . . I asked questions and he kept talking"). Sarcasm may be used as a coping strategy, especially if that is the victim's usual verbal style.

> As he was molesting me he asked if I enjoyed it and I said, "Oh, sure, it is great." I decided to go along with him. He seemed to need reassurance . . . I wasn't scared then. First thought he'd get his kicks and then it'd be all over—I'd be dead. I got faith that he wasn't going to harm me.

Some victims tried to gain control in the situation by scaring the assailant(s) ("You'll be in real trouble if you kill me"; "You'll be sorry . . . I'll get someone to kill you"). This strategy was partially successful in some cases.

Physical Action

Victims reported struggling and fighting with their assailants to avoid penetration ("I struggled and tightened my muscles"). Sometimes the victim struggled to a certain point and then stopped ("I fought and struggled until I realized he was going to rape me. He wanted to rape me more than I could manage to resist"). Some victims quickly discovered that struggling and fighting were just what the assailant wanted ("The more I screamed and fought, the more excited he would get").

Psychological Defenses

Defense mechanisms are another way rape victims cope with the overwhelming fear of attack. Defenses close the cognitive field and thus block out the unbearable feeling. Some women denied the attack ("I never thought it could happen"), experienced dissociative feelings ("I pinched myself to see if I was real"), suppressed the rape ("I am missing 10 minutes of my life"), or rationalized ("I felt sorry for him if this was the only way he knew how to get sex"). One victim described her reaction as follows: "I did not struggle because of the knife. All those things you read about or plan to do don't help . . . I felt I was not going to get out alive . . . I was resigned; I felt nothing, empty; felt this can't happen to me."

Physiological Response

Not all coping behavior is voluntary and conscious. Certainly, some screaming and yelling is involuntary, and victims also reported physiological responses of choking, gagging, nausea, vomiting, pain, urinating, hyperventilating, and losing consciousness. One victim described an epileptic seizure:

> Only thing I remember is getting the key into the lock to get into the building. Then I got warning signs to my seizure attacks . . . getting overheated and the ringing in my ears and that's all. When I regained consciousness I was in the hall by the door to the basement. I dragged myself out as I heard someone saying, "Who left their keys in the door?"

Another victim described how her involuntary reaction scared the assailant off after he raped her: "I felt faint, trembling and cold . . . I went limp. I think he got scared and thought I was out."

AFTER THE ATTACK: ESCAPING FROM THE ASSAILANT

The stressful situation is not over when the actual rape ends. The victim must alert others to her distress, escape from the assailant, or free herself from where she has been left. The coping task immediately following the rape is to be free or escape from the assailant.

Alerting others. Victims are always hopeful that someone will come to their aid, and they may spend time concentrating on how to obtain help.

Bargaining for freedom. Often, the victim must negotiate with the assailant through a bargaining process. The assailant sometimes apologizes and tries to gain sympathy and thus get the victim to promise not to tell, or he may give the victim orders or instructions

("I'll kill you if you tell or go to the police"; "Don't move from that position for 30 minutes"). During the bargaining process the victim may cope by remaining silent or agreeing to instructions. Some victims promised not to tell anyone or invented stories to preserve their lives: "I told him my girl friend had this happen and when she went to the police they didn't believe her. I told him I'd never go to the police."

Freeing oneself. The victim may have to free herself from the situation—if she has been tied and gagged, she has to cope with physically freeing herself. Cognitive assessment of the situation and keeping calm will be most useful strategies to her, as was the situation in the following referral case: "I lay still for a moment . . . then realized that the faster I got myself untied, the faster I could get to the police and my friends . . . ankle ties . . . getting cramps in my legs . . . so I had to tell myself not to panic and I worked the wrist ties and ankle ties next . . .."

Mastery, in terms of survival of the attack, may be verbalized by the victim as well as her family and friends when this stage has been managed successfully: "The worst is over . . . I got through it . . . I am grateful to survive."

Once free of the assailant, the victim must still cope with the stress of the aftermath of the rape. Victims are often immediately faced with trying to cope with the institutions that are set up to deal with rape (16).

COUNSELING IMPLICATIONS

Understanding a person's coping behavior when faced with a life-threatening situation is an essential step in crisis intervention. Rapoport (17) noted that patterns of coping in crisis situations may be adaptive or maladaptive. Parad and Resnik (18) stated that the purpose of actively focused crisis intervention is to steer the person toward adaptive coping and away from maladaptive behavior. Adams and Lindemann (19) formulated coping principles drawn from a study of catastrophic disabling injuries; they emphasized identifying the acute crisis and the psychological means by which the crisis is to be managed if not mastered.

The assessment of coping behavior and strategies provides the clinician with two therapeutic measures. First, such assessment can be used as a supportive measure. By listening to the victim recount the rape, clinicians can identify the coping behavior and acknowledge this information to the victim. This support tells victims that their coping behavior was a positive adaptive mechanism used to survive a life-threatening situation. By verbally conveying this information, the clinician attempts to alleviate some of the guilt suffered by a victim who may think, "I did not do enough—I could have done more." This therapeutic approach sets in motion a positive sense of self-esteem and worth. As was noted by one victim, who was raped by two assailants at knife point, "At least I wasn't so whacked out that I couldn't get a description and license of the car." Reaffirming the strategic use of her cognitive abilities helped this victim to see herself as a person who was able to *do* something in a highly stressful situation, even though she was physically immobilized. Such a response by the clinician strengthens the therapeutic alliance in terms of providing positive expectations regarding the victim's capacity to restore herself to her precrisis level of functioning. Thus we see that Murphy's model of resilience (20), wherein a person sees herself as someone who is resilient and expects to recover from the trauma, has significance in counseling rape victims.

The second use of assessment of coping behavior is to give the clinician a reference point from which to begin the clinical negotiation for crisis service (21). As the victim states her request and it is negotiated, additional requests may be elicited. For example, one request may be related to primary prevention in terms of what other strategies might be used in such situations. The clinician can explore with the victim the crisis behaviors she used and analyze their effectiveness. New strategies might be suggested as possibilities in future stressful situations. It is important to help expand the person's problem-solving capabilities (22).

We believe our analysis of the coping behavior of rape victims opens up other research areas. There are two questions of major importance: 1) what coping strategies seem to result in less psychological trauma after a rape? 2) What additional therapeutic techniques are needed to aid the rape victim?

Development of a Medical Center Rape Crisis Intervention Program

BY SHARON L. MCCOMBIE, M.S.W., ELLEN BASSUK, M.D., ROBERTA SAVITZ, M.D., AND SUSAN PELL, R.N.

The Rape Crisis Intervention Program at Beth Israel Hospital utilizes volunteer multidisciplinary counseling teams drawn from psychiatry, social work, psychology, and nursing staffs. The premise of the program is that early crisis intervention can prevent later development of psychological disturbances in victims. Counselors accompany victims throughout emergency room procedures; follow-up begins 48 hours after the initial contact and continues at regular intervals for at least a year. The authors discuss the problems of implementation, which include staff resistance, funding questions, and varying levels of counseling sophistication, and describe how these difficulties have been handled in their program. They note that this program is becoming a resource center for the community.

RAPE is a physical, social, and psychological attack upon the person. It is the fastest rising violent crime in the United States: the FBI reported a 68% increase in rape (from 31,000 to 51,000 cases) between 1968 and 1973, and police figures in Boston show a 43.5% increase between 1972 and 1973 (1).

Rape has been viewed primarily as a sexual rather than a violent assault. The traditional assumption is that the woman in some way invited the attack. This attitude obscures recognition of the trauma experienced by the victims and interferes with the development of adequate community and institutional resources to treat them. This is reflected in the absence or fragmentation of medical and psychological care for rape victims.

In response to this problem, a comprehensive support system for the rape victim has been developed at the Beth Israel Hospital, a metropolitan teaching facility oriented toward community medicine. Particularly in urban areas, hospital emergency rooms are the typical health care facility utilized by victims at the time of the rape. Prior to the development of our project, emergency room records showed that an average of one victim a week received medical care during 1972–1973. The psychiatric service was consulted only if the victim presented a management problem for the emergency room staff. Follow-up was generally inconsistent. Clinicians were impressed, however, by the number of women who appeared at the Psychiatry Clinic months or years later for whom the rape was a major component in the presenting symptomatology. At the time of the assault, these women had not sought psychiatric assistance. Indeed, many had never told anyone about the rape.

The Rape Crisis Intervention Program is based on the premise that early intervention can prevent the development of psychological and psychosomatic distur-

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with Beth Israel Hospital, 330 Brookline Ave., Boston, Mass. 02215, where Ms. McCombie is Director, Rape Crisis Intervention Program, Drs. Bassuk and Savitz are Assistants in Psychiatry, and Ms. Pell is Head Nurse, Inpatient Psychiatric Unit. Drs. Bassuk and Savitz are also Instructors in Psychiatry, Harvard Medical School, Boston, Mass.

bances. The program's aim is to integrate and expand available medical services and provide psychiatric crisis counseling (2). This paper will describe some of the problems encountered in implementing such programs in a medical setting.

RAPE AS A LEGITIMATE HEALTH ISSUE

There is both community and hospital resistance to recognizing rape as a legitimate health issue requiring medical and psychological services. In the past, the psychiatric community has not participated in providing resources for victims. Throughout the country, most services come from grass roots women's organizations, which often view psychiatry as a male-dominated, pathology-oriented profession that stigmatizes the victim by labeling her a mental patient.

Because hospitals have only recently acknowledged the needs of rape victims, feminist organizations have tended to regard these institutions as part of the problem. These women's groups have attempted to minimize the victim's contact with health professionals by establishing alternative facilities. However, there is no way to bypass the necessity for professional gynecological services. The medical, surgical, and psychiatric resources of the emergency room, their 24-hour availability, and the legal requirement for medical evidence bring the victim into the health care system. Because of the multidisciplinary make-up of the general hospital, it is a potential center for comprehensive treatment of both the physical and emotional needs of the rape victim.

Hospital resistance to mobilizing supportive services can be traced to two major sources. First, staff prejudices about rape can jeopardize the respectful, thorough treatment of the victim. Second, staff working in a treatment model geared to respond to medical and surgical emergencies may underestimate the significance of emotional crises. If the woman does not exhibit wounds that testify to her victimization and unambiguously signal her need for medical assistance, her status as a legitimate consumer of health services may be questioned. Regardless of the presence or absence of physical injury, the emotional trauma of forced violation—frequently under threat of death—establishes the victim's right to sensitive professional care.

PROGRAM DESCRIPTION

There have been four major objectives in the implementation of our service for rape victims:

1. Providing both immediate and follow-up counseling that is aimed at resolving the psychological crisis.
2. Encouraging emergency room personnel to respond sensitively to the emotional needs of the victim.
3. Developing an understanding of the special needs of this patient population in order to provide expert consultation to community and professional groups.
4. Conducting research on the acute and long-term impact of rape on life adjustment.

There are still many unanswered questions about the psychodynamics of rape trauma and the adult victim's reactions and long-term adaptation (3–5). To provide quality crisis counseling and assessment and to gather sound clinical observations, we needed mental health clinicians on the staff of our program. Because of this need and the funding problems we encountered, a volunteer counselor roster was organized. The counseling team is a self-selected group of volunteer personnel from psychiatry, social service, psychology, and nursing. This multidisciplinary approach distinguishes our program from the single-discipline model used in other hospitals (6, 7).

Training and supervising a multidisciplinary group of volunteers is complicated by the various levels of counseling sophistication that are represented in the team. Individual learning needs are addressed in weekly supervisory sessions based on the model used for teaching psychotherapy. All members of the counseling team are required to attend a series of weekly didactic seminars on crisis intervention techniques and the special problems of rape victims. Nurses, gynecologists, and other interested hospital personnel are encouraged to attend these meetings.

The volunteer model has proved to be cumbersome, unreliable at times, and difficult to coordinate. However, it has had the advantages of sensitizing a large number of hospital personnel to the emotional needs of the rape victim and of encouraging awareness of psychological issues in the treatment of all general hospital patients.

The 24-hour on-call system ensures that a counselor will be available to accompany the victim throughout all emergency room medical procedures. The initial role of the counselor is to provide emotional support and information to the victim. The counselor also meets with friends or relatives who have accompanied the victim to discuss their concerns and mobilize their support. Follow-up begins within 48 hours after the initial emergency room contact. Subsequent contacts are made at regular intervals for at least 1 year. The frequency and content of the intervention is based on the needs of the victim, as determined by clinical assessment and timing of anticipated periods of exacerbation of symptoms, such as court appearances.

The counseling goal is to increase the individual's adaptive capacity by delineating and working through the crisis-related issues. If the victim has unusual difficulty resuming her precrisis level of functioning, she is referred for psychotherapy.

ORGANIZATIONAL INTERFACES AND POLICY ISSUES

Official sanction from the Department of Psychiatry was crucial to the implementation of our program.

Staff time was requested for the recruitment, training, and supervision of the counselor team. Initially, there was hesitation about supporting the program because of the demands on staff time. There was also a tendency to see rape as a social problem rather than as a crisis warranting psychiatric intervention.

Since crisis intervention techniques could be taught with rape counseling as a model, the program was consistent with the Psychiatry Department's commitment to training and its active hospital liaison program, which integrates psychological understanding with patient care (8). At the same time, the growing public awareness of the needs of women helped to offset objections stemming from the controversial nature of our target population.

The chiefs of social service, nursing, and medicine were approached to enlist their cooperation in personnel training and coordination of service delivery. This initiated a continuing dialogue with these departments carried on through periodic visits to their staff meetings.

In order to establish administrative backing, we had to develop a policy regarding payment for counseling services. Currently, the woman is charged the routine fee for the emergency room visit and is not billed for the counseling services. The cost is absorbed by the hospital as loss of staff hours from the professional volunteers' regular duties.

There is a continuing debate as to whether the hospital, the community, or the victim should be responsible for the costs incurred. One argument is that, as in all preventive health care programs, the treatment of rape victims is cost effective in the long run. However, because of the economic recession and the rapidly rising overhead of hospitals, each program must demonstrate its cost effectiveness.

A variety of complex factors must be considered before an optimal financial policy can be determined. These include the following:

1. The majority of the victims are young, single women with low incomes, inadequate health insurance, and doubtful ability to pay.
2. Some of the medical procedures are for the collection of evidence for the state's case against the alleged criminal rather than for the victim's health care.
3. There is clinical concern about the meaning transmitted to the victims when they are set apart from other consumers of health care who pay for services.

GYNECOLOGY AND EMERGENCY ROOM LIAISON

We have emphasized liaison with the gynecology and emergency room staffs. The mechanics of the gynecological examination are usually handled with skill (9). However, anxiety about how to respond to a woman who has just been raped can lead to staff withdrawal or denial of the event. Female staff members are reminded of their own vulnerability. Male staff members become acutely conscious that they may be the first man the victim sees after the rape. The victim's anger and helplessness are frightening, and there is a tendency to counterattack or to infantilize.

The medical examination of the rape victim occurs in the interface between the health and legal professions, since the physician's findings may become evidence in a court of law (10). Since the doctor can be required to give testimony, he may hesitate to become involved or may respond by trying to judge for himself whether the case is a "real" rape.

The protocol of the American College of Obstetricians and Gynecologists for the examination of rape victims is a detailed procedure for the gathering and preservation of specimens for evidence (11). It has the advantage of providing complete and careful documentation. Nevertheless, in the pressures of the emergency room, it may be regarded as a tedious chore. Other factors affecting the physician's response to the rape victim are his concept of his professional role, his personal feelings about rape, and his attitudes toward the legal and penal systems.

Gynecology and nursing meetings have been used as forums to identify and discuss staff concerns. Treating victims of violent sexual assault is openly acknowledged as stressful. Through the use of videotaped interviews with victims, role playing, and discussion, personnel are sensitized to the stresses the victim experiences in the emergency room.

When a woman who has recently been raped takes on the label of patient, she is assuming a role characteristically associated with being damaged and helpless. The victim-as-patient assumes a status that reinforces the helplessness and fears about being damaged that are natural sequelae of the rape experience. Her physical and emotional pain become tangible reminders of her inability to protect and to defend herself. The confusion and lack of privacy in the emergency room can prolong and compound her discomfort. A pelvic examination done abruptly can be experienced as a repetition of internal invasion. The hospital becomes an institutional transference object upon which both negative and positive feelings are focused. The staff must be equipped to deal with the intense affects aroused and to help the victim work through them. The rape crisis counselor is a consultant to medical and nursing staff in the emergency room, and his/her interpretation of the victim's behavior and empathy with the medical staff's feelings reduce anxiety and enhance sensitive treatment of the patient.

The introduction of a new program staffed by nonemergency-room personnel into the routine emergency room system has presented several unsolved problems. For example, while our counselors relieve the nurses of certain pressures and responsibilities, there is also a mixed message about the nurses' role and competency. Although we have explicitly invited them to be trained as rape counselors, few are able to do so because of the demands of their regular duties. We have approached this difficulty by including an emergency room nurse as a member of the program's ad-

ministrative and planning group; this has resulted in an improved cooperative team effort and, secondarily, has supported nurses' continuing efforts to expand their role.

DISCUSSION

Although our program is still in the experimental phase, progress has been made in establishing rape as a legitimate health issue and in including the care of rape victims among the repertoire of services provided within a medical center. The liaison work has been essential in successfully setting up a multidisciplinary program of this kind. The most important interfaces have been with the Departments of Psychiatry, Nursing, and Gynecology. Our continuing dialogues with these departments have emphasized the generalizability of our crisis approach to other patients.

As organizational issues are settled, the program will increasingly concentrate its efforts on developing research on the long-range resolution of the rape crisis and will attempt to differentiate the implications for women at various stages in the life cycle. This information is critical for optimally effective service and for evaluation of the preventive impact of early intervention on later adjustment. The didactic series used in teaching our counselors is being refined and compiled into a training manual for use by other hospitals. The Rape Crisis Intervention Program is rapidly becoming a resource center for the community through consultation and education programs for police, educators, health professionals, and the public. Our aim is to encourage and assist other community medical facilities in providing a support system for women dealing with this life crisis.

Assaults on Psychiatrists by Patients

BY DENIS J. MADDEN, PH.D., JOHN R. LION, M.D., AND MANOEL W. PENNA, M.D.

The authors describe the results of a survey of 115 psychiatrists regarding assaults by patients. Forty-eight psychiatrists stated that they had been assaulted; a total of 68 assaults was reported. Psychiatrists were most often assaulted in the early stages of their career or while they were working in high-risk settings such as prisons or emergency rooms. Many reported retrospectively that they might have had a role in provoking the assault and that they could have anticipated it. The authors believe that psychiatrists avoid dealing with the issue of violence by patients for a variety of reasons, and they recommend that clinicians learn techniques for managing potentially assaultive patients.

THE RECENT American Psychiatric Association Task Force Report on Clinical Aspects of the Violent Individual (1) referred to a number of published studies regarding assaults on psychiatric staff within mental hospitals (2–8). These reports dealt for the most part with assaults by psychiatric patients on other patients or on staff personnel.

Ekblom (4) was able to review the literature on acts of violence by psychiatric patients from 1889 to 1970 in 2½ pages, which suggests that the literature is sparse. Ekblom cited only one study, by Kolle (4, p.10), which suggested that the attitudes of physicians and nursing staff might provoke acts of violence. Kalogerakis (5) reported incidents of assault and attempted to make psychodynamic and sociological interpretations in each case.

Our work with violent patients led us to question whether psychiatrists might either overtly or covertly provoke the violent behavior of their patients. This hypothesis, in addition to the lack of substantive data in this area, led us to undertake the present study.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with the Clinical Research Program for Violent Behavior, Institute of Psychiatry and Human Behavior, Department of Psychiatry, University of Maryland School of Medicine, 6465 W. Redwood St., Baltimore, Md. 21201, where Dr. Madden is Clinical Assistant Professor, Dr. Lion is Associate Professor, and Dr. Penna is Assistant Professor.

This study was supported in part by the Foundation for Clinical Research in Psychiatry, Inc., Baltimore, Md.

METHOD

We surveyed by questionnaire 115 psychiatrists who held full or part-time clinical appointments at the University of Maryland School of Medicine. This group represented a variety of clinical and administrative positions, including private practice, mental health clinics, medical school appointments, forensic and prison settings, and state hospital positions. Each psychiatrist was sent an initial questionnaire asking whether or not he had in the course of his career been assaulted by patients and what the nature, timing, quality, and other characteristics of the assault had been. Respondents who indicated that they had been assaulted were then interviewed personally or by telephone to elicit more data regarding the nature of the assault, the patient's diagnosis, and level of therapeutic involvement with the patient by whom they were assaulted.

In addition to sampling our own faculty, we published letters in the August 21, 1974, issue of *Psychiatric News* and the November 1974 issue of the *American Journal of Psychiatry* requesting information on assaults. As a result of these letters we received 15 responses relating 20 incidents of assault.

RESULTS

Although all of those sent the questionnaire did not respond to our first inquiry, a second questionnaire and phone calls resulted in a 100% response.

Of the 115 psychiatrists sampled, 48 responded that they had been assaulted, and 67 reported that they had never been assaulted. The total number of assaults reported in questionnaire responses was 68.

Psychiatrists who reported being assaulted varied considerably in age and level of experience, but most of the assaults occurred when clinicians were in early phases of training. The majority of psychiatrists were assaulted by patients who were in active treatment, and most of these therapists continued to see their patients after the assault occurred.

Some vignettes can give an indication of the type of incidents reported to us. In the following case there had been a long therapeutic involvement prior to the assault.

Case 1. The patient, a 41-year-old male, had been in therapy for 2 years. He had had several earlier attacks of psycho-

sis, during which he did bizarre things, but there was no record of previous violent assaults. At the end of one session, the therapist was saying good-bye when the patient suddenly lashed out with his right fist, catching the therapist on the jaw. One week later, while the therapist was writing a prescription, the patient stabbed him with a pin in the left thigh. The patient was emotionally upset and embarrassed, as he had been after the first attack. He indicated that the pin-stabbing signified a desire to be given an injection, since this had helped terminate a previous acute psychotic decompensation rapidly. He also saw the jabbing as a confused expression of dissatisfaction with the therapist, who had not made him well fast enough.

Another assault occurred when the therapist had had no contact with the patient.

Case 2. The patient was a 30-year-old male who had been hospitalized with a diagnosis of acute paranoid schizophrenia but had no history of violent behavior. The therapist was just beginning his 3-month rotation on psychiatry as an intern. He and eight other staff members were attempting to restrain a patient who had attempted to rape another patient and had hit several orderlies who tried to stop him. While this was taking place the assaulted patient suddenly grabbed the doctor from behind in a head lock. It was later learned that this patient thought that he was God and believed that the patient who had attempted to rape him was one of his "disciples." He felt the need to protect his disciple and grabbed the first "enemy" he came to.

Characteristics of Patients and Therapists Involved in Assaults

Table 1 summarizes the results of the survey. Psychiatrists who were assaulted usually sustained only minor injuries. However, one senior psychiatrist reported that he had been shot in the chest. A paranoid patient came into the therapist's office and informed him that he had to shoot him in order to stop some other doctors from giving him "bad medicine." The wound did not seriously injure the therapist, and he was able to resume his practice in a few weeks. Another serious injury was reported to us by a therapist who had had his nose fractured by a patient.

Table 1 also gives a breakdown of the types of assaults reported. Most were a slap to the face or a blow on the head. Some psychiatrists reported having objects such as an ash tray or other object from their desk thrown at them. One patient tried to set the therapist's clothes on fire, and another therapist was tied up by a group of patients. There was one report of an amorous "attack," in which the patient tried to kiss the therapist in what was perceived by the therapist as an inappropriate and assaultive manner.

The majority of patients who assaulted psychiatrists were judged to be psychotic, with diagnoses ranging from paranoid to catatonic schizophrenia. A smaller number were diagnosed as having borderline or personality disorders. The remainder of assaultive patients were diagnosed as alcoholic, hyperactive, and adjustment reactions. One patient (included in the "other" category) was diagnosed as depressed. The majority of patients were young; we encountered few older patients who assaulted physicians.

TABLE 1
Characteristics of 68 Assaults by Patients Reported by 48 Psychiatrists*

Attitudes of Therapists toward Assault

We also questioned the therapists regarding their retrospective anticipation of the assault. This question, although somewhat nebulous, indicated our interest in the role of therapists in provoking assaultive responses on the part of patients. Fifty-five percent of the respondents reported that they could have anticipated the assault, and 53% felt they had acted in a provocative manner. A majority of the therapists felt that they could have anticipated the assault because they had made comments or interpretations that were unfavorably received by the patients. One therapist resented the notion that he or other therapists might have acted in a provocative role and compared this to viewing the rape victim as the provoker. He felt that society, the Viet Nam war, and the prevailing culture were more responsible than individual therapists for such assaults.

We asked clinicians what they thought triggered particular assaults. Among the responses received were: refusing to meet a patient's request, forcing a patient to take medication, setting too many limits or not setting enough limits, transference reactions, homosexual

panic, and the material being dealt with in therapy. Many therapists felt, at least in retrospect, that they had been at times too insistent that a patient confront upsetting material. Such therapists felt that the incident might not have occurred if they had backed off. Several therapists reported candidly that they did not particularly like the patient who assaulted them and might have projected this feeling to the patient. One therapist reported that after a patient had asked him five times to write a letter for him he responded in a flippant way that if the letter was so important the patient should write it himself.

In addition to asking what might have precipitated the particular assault reported, we asked what the respondents thought caused assaults in general. Inexperience and fear of patients, which at times are translated into an omnipotent facade, were mentioned by several of the clinicians interviewed. One senior psychiatrist said that it had been his experience that those residents who allowed patients to act out in therapy sessions were the ones who were most frequently assaulted. On a more personal level, some of the clinicians felt that therapists might act in a seductive manner, project an unconscious expectation that an assault will take place, or attempt to veil an underlying hostility with kindness, all of which can lead to assaultive behavior on the part of the patient. The following incident demonstrates how the feelings of the therapist may at times enter into an assault.

Case 3. The patient, a 30-year-old male, had been transferred from another hospital with a diagnosis of paranoid schizophrenia. He was one of the first patients that the therapist had treated as a resident. The patient had been in treatment for about a year, and during that time the therapeutic relationship had been a difficult one for the therapist. The patient exhibited much hostility and directed much sarcasm toward the therapist. Just prior to the attack, the patient had requested a pass to return to an area where he had been involved in inappropriate financial deals. At the same time the therapist was preparing to go on vacation. When the patient was told that he would not be given the pass he became furious and verbally threatening. The therapist was extremely anxious and also experienced difficulty in dealing with his own anger. During this stormy session the patient grabbed the therapist's shirt and tie and had to be restrained by an aide. In retrospect, the therapist felt he had been angered by the patient's persistent attacks on him, which had included critiques of his personality, mannerisms, dress, religion, and other aspects of his life. The therapist viewed the patient as one of the "nastiest" persons that he had ever encountered, clinically or otherwise.

Some clinicians were assaulted on several occasions. Several psychiatrists who sustained multiple assaults worked in rather dangerous settings, such as prisons, forensic units of state hospitals, or emergency rooms, where the potential for incidents of assault was higher. One physician from an indeterminate sentence facility prison hospital was assaulted on numerous occasions and commented that assaults on staff were quite common.

DISCUSSION

The finding that 42% of the clinicians surveyed reported having been assaulted by a patient was interesting and surprising to us. It is surprising because we believe that the majority of psychiatrists are attracted to psychiatry, on at least a theoretical level, because of its contemplative nature and its use of verbal skills rather than physical management as the primary tool for treating patients. This is in contrast to other medical specialties, in which physical handling of patients is more prevalent.

It seems reasonable to suggest that there are high-risk areas where psychiatrists stand in jeopardy of being assaulted by patients about whom they make decisions regarding incarceration, continued incarceration, or commitment. However, as our study shows, assaults were not limited to these individuals but also occurred among physicians who were in private practice and in a variety of other, less dangerous occupational settings.

It is our belief that denial plays a heavy role in both the ways clinicians deal with patients who might be assaultive and their recollection of assaults. One clinician who had been threatened many times by a patient and had tape recorded these threats on his life was still hesitant to take any action to prevent a potential assault. The alarming nature of patient assault on clinicians is brought home by reports of two psychiatrists who were killed by patients within the last two years. One psychiatrist on the staff of a state hospital in the Boston area was killed while attempting to disarm a patient, and another psychiatrist in New Haven was killed by a patient he had seen on only one occasion. According to several questionnaire respondents who mentioned the incident, this patient apparently incorporated the psychiatrist into a well-developed paranoid delusional system and then shot him.

Few clinicians thought assaults had occurred without their own involvement or on a random basis. Those who reacted defensively and blamed the patient or the setting for the assault usually worked in prison or forensic settings, where they were exposed to a large number of antisocial assaultive patients over whom they had little control and with whom they had little therapeutic relationship. One clinician who worked in a prison reported that he carried a gun to protect himself from threats of assault, even though he had only been assaulted twice. Another clinician who was exposed to an equally dangerous group of patients in a criminal court system had never been assaulted and had in the entire course of his ten-year career been threatened on only one occasion. A psychiatrist in private practice was assaulted several times, and a clinician in a state hospital for the criminally insane had sustained several assaults and looked upon them in a more or less philosophic fashion as part of the line of duty.

In our work with violent patients we have focused on countertransference reactions to such patients and

the anxieties, denial, and projection that clinicians experience when working with such individuals. It is difficult to ascertain the degree to which transference phenomena occurred among patients, but the vehement responses of several clinicians to our study indicated that they were very angry with several patients who could be classified as violent and did not wish to deal with them. Some clinicians are obviously more sensitive and skilled in the management of aggressive individuals, but there are also superimposed social and cultural factors that play a role in therapists' dislike and avoidance of violent patients.

It is our belief that the subject of violence among psychiatric patients tends to be minimized for a variety of reasons, both conceptual and psychodynamic. First, psychiatrists are apt to be more in tune with the internalization and introjection of aggressive urges and thus they may reward patients who show depressive symptoms, which they consider more treatable than aggressive ones. This leads to a shunning by clinicians of violent patients and, we believe, a distinct lack of training and expertise in the management of assaultive individuals. Not all assaultive patients are suitable candidates for treatment, and the management of assaultive patients is best carried out in crisis situations by people skilled in physical restraint techniques (3).

We believe that more attention should be paid to assessing on a clinical basis a violent patient's propensity toward acting out in a transference situation. We also feel that clinicians must become more sensitive to their role in dealing with potentially violent patients so that they can institute effective intervention policies.

Assault on the Therapist

BY ROY M. WHITMAN, M.D., BEATRICE B. ARMAO, M.S.W., AND ORAN B. DENT, PH.D.

The authors conducted a questionnaire survey among psychotherapists in psychiatry, psychology, and social work to determine how many patients posed a threat to others or to the therapist and how many actually assaulted the therapist. They found that 9.2% of all patients seen by 101 therapists in one year presented a threat to others, 1.9% posed a physical threat to the therapist, and .63% actually assaulted the therapist. The authors conclude that attacks on a therapist are infrequent but almost inevitable and suggest the development of techniques for coping with assaultive patients that therapists can use in crisis situations.

WE FIRST BECAME INTERESTED in the subject of assaultive patients when one of us (B.B.A.) reported during a supervisory consulting session that she had been threatened by a potentially violent patient. The literature offered little information concerning therapists' fears of assaultive patients; neither did our associates. It appeared that the subject was often ignored during training and that it did not arise very often in consultation.

Our discussion of the situation raised several questions: How many other therapists are similarly threatened? How do they handle both the patient's and their own feelings? Do level of training and experience make a difference in the clinical approach to these problems?

We were surprised at the variations in our colleagues' responses to questions about assault. A number of them said that they had never been frightened or assaulted by a patient, but more recalled incidents that had happened recently or some years past. The willingness of some therapists to relate in detail dramatic incidents in which they had been involved was impressive.

Therapists then came to us with more experiences not recalled at first inquiry. Recall and subsequent discussion had a cathartic value for them. Our interest was further augmented by the fact that incoming trainees were encountering threatening patients. The pooled clinical experience of therapists and trainees suggested that impulsive, violent patients were being seen more frequently in mental health facilities than ever before. It seemed to us that the Viet Nam experience, for example, had left many of our veteran patients with residual rage that was poorly controlled.

The literature on assaultive patients that we surveyed (1, 2) tended to emphasize countertransference on the part of therapists and to deemphasize realistic fear reactions. Lion and Pasternak (1) commented that therapists have "some anxiety about treating a violent patient," but the main emphasis of their paper was that the physician distorts and exaggerates the patient's dangerousness by means of projection.

Macdonald (2) studied how seriously the therapist or other evaluator should take homicidal threats toward others; we are asking how seriously a therapist should take threats toward himself. Should he be afraid or not? What does the therapist feel when he is threatened with assault? How does he cope with the patient and his own feelings?

METHOD

We sent a questionnaire[1] to 184 mental health workers in the three professions of psychiatry, psychology, and social work in the Cincinnati, Ohio, area. The respondents could remain anonymous if they wished. The questionnaire requested information on the discipline of the therapist, number of years in practice, and number of patients seen during the calendar year 1972. Questions were then directed toward the number of patients seen during the year who the therapist felt posed physical threats to others, the number who the therapist felt posed threats to himself, and the number who actually assaulted him. We then requested a narrative description of the most frightening experience the therapist had had with an assaultive patient in 1972. If he had had none that year, we asked for an account of an experience from any time during his professional career. We asked for the strategies that the therapist used to deal with the situation described, the therapist's reactions, and the final outcome of the event.

Revised version of a paper read at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Address reprint requests to Dr. Whitman at the University of Cincinnati College of Medicine, 231 Bethesda Ave., Cincinnati, Ohio 45267.

[1]Copies of the questionnaire are available on request from the authors.

One month after our initial mailing, we circulated the same questionnaire again to the same group, urging them to fill out the form if they had not already done so.

RESULTS

Seventy-eight of the 184 therapists (42%) responded to the first mailing. The second mailing increased the total number of responses to 101 (55%). Of the 96 psychiatrists contacted, 53 (55%) responded; 27 of 43 psychologists (63%) responded; and 21 of 44 social workers (48%) responded.[2] Thus 52% of the sample of 101 therapists were psychiatrists (the ratio of residents: staff was 17:36), 27% were psychologists, and 21% were social workers. These percentages approximate the relative numbers of active psychotherapists in the Cincinnati area for the three disciplines.

Twelve of the respondents were from the University of Cincinnati Counseling Center, 14 from the Northern Kentucky Comprehensive Care Center, and 75 from various settings (including 17 in private practice) affiliated with the University of Cincinnati Department of Psychiatry. Of the 101 respondents, 80 worked primarily in outpatient settings and 21 in inpatient settings.

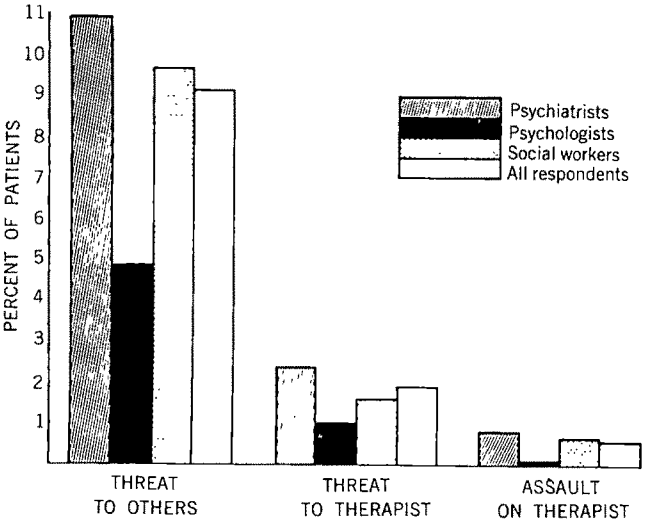
The psychiatrists were more experienced as a group and saw more patients than either psychologists or social workers. The range of experience for psychiatrists was 1–40 years, with a median of 5 years' experience; psychologists reported 1–22 years' experience, with a median of 4; and social workers had 1–20 years' experience, also with a median of 4. All three disciplines reported a full range for number of patients seen. Psychiatrists, however, reported a median of 81–100 patients seen, while both psychologists and social workers reported a median of 41–60 patients. Our findings reflect a population in which the psychiatrists were older and saw more patients than psychologists or social workers. A surprising number of therapists reported that they had seen more than 100 patients during the year (24 psychiatrists, 3 psychologists, and 4 social workers). In estimating the total numbers of patients seen, the 1–20 category was counted as 10 patients, 21–40 as 30, and so forth.

As shown in figure 1, of the 3,810 patients seen by the 53 psychiatrists during 1972, 416 (10.9%) were perceived as presenting some assaultive threat to other people in their environment, 91 (2.4%) posed some physical threat to the therapist, and 33 (.87%) actually assaulted the therapist. The 27 psychologists reported that they had seen 1,740 patients and that 85 (4.9%) presented some threat to others, 18 (1.0%) posed some threat to the therapist, and 2 (.11%) assaulted the therapist. Twenty-one of the social workers reported that they had seen 1,170 patients and that 114 (9.7%) presented some threat to others. Twenty of the social workers reported that 17 of 1,000 patients (1.6%) posed some threat to the therapist and that 7 of 1,070 patients (.65%) actually assaulted the therapist.

Of the total of 6,720 patients, 615 (9.2%) presented some assaultive threat to others, 126 (1.9%) posed a physical threat to the therapist, and 42 (.63%) actually engaged in assaultive behavior toward the therapist. A major finding of this study thus emerged as a ratio—patients who presented threats to others: those presenting threats to the therapist: those who assaulted (15:3:1).

As shown in figure 2, 79% of the total group of 101 therapists (77% of 53 psychiatrists, 81% of 27 psychol-

FIGURE 1
Percents of Patients Who Posed Threat to Others or to Therapist or Who Assaulted Therapist



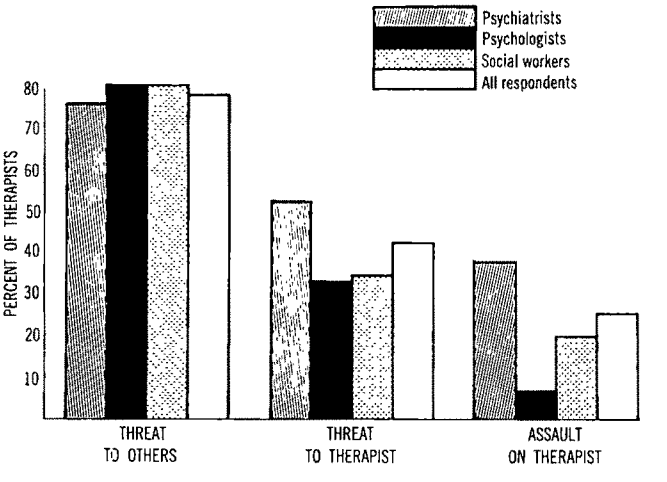


FIGURE 2
Percents of Therapists Who Reported Having Seen One or More Threatening Patients in 1972

[2]One of the responses from a social worker was incomplete: this respondent reported data on 100 patients and answered only the questions on how many of these patients posed some threat to others and whether he had ever been assaulted by a patient in the past.

ogists, and 81% of 21 social workers) reported at least one incident in which a patient was perceived as presenting some threat to others. Forty-three percent of 100 therapists (53% of 53 psychiatrists, 33% of 27 psychologists, and 35% of 20 social workers) reported at least one incident in which the therapist felt personally threatened. Twenty-four percent of 100 therapists (34% of 53 psychiatrists, 7% of 27 psychologists, and 20% of 20 social workers) reported that they were actually assaulted during the year by one or more patients.[3] No psychologist reported more than one assault for the year, but 8 (15%) of 52 psychiatrists and 1 (5%) of 20 social workers reported two or more. Although the percent of patients who actually attacked therapists is low (less than 1%), the likelihood that a therapist who sees a large number of patients will be assaulted is strong.

A series of chi-square tests were performed to investigate relationships within the data.[4] No differences were found between staff and students for personal threats and for actual assaults. Staff psychologists and psychiatrists reported a significantly smaller percent of patients who presented threats to others than student psychologists and psychiatrists ($p<.05$), but a comparison of staff and student social workers showed no difference.

Divided at a median of 9 years, the effect of number of years of experience of staff psychotherapists (those with more than 3 years' experience) was investigated for each of the three threat categories; no differences were found.

Differences for the setting in which the therapists worked were also investigated. The only finding was a disproportionately low number of personal threats felt by the therapists at the University of Cincinnati Counseling Center, who were working with a population of college students.

No significant differences were found among psychiatrists, psychologists, and social workers for the percent of cases reported in the three threat categories. Likewise, no significant differences were found in a comparison of male and female therapists.

As might be expected, the more patients seen by a therapist, the more threats were reported in each of the three categories. Furthermore, the more patients a therapist reported as posing threats to others, the more patients he felt posed a threat to himself; and the more patients he felt posed a threat to himself, the more patients actually assaulted him.

Seven major categories of coping techniques emerged from the therapists' descriptions of assaultive incidents. The research team added an eighth technique. These techniques are: 1) interruption of the interaction, 2) physical restraint, 3) nonverbal minimization of self as threat, 4) verbal responses, 5) protection of self, 6) encouraging motoric discharge of anger, 7) assistance from supervisors and/or colleagues, and 8) countertransference maneuvers. These coping techniques, as well as the reactions of therapists to assault and the final outcome of the event, will be discussed in more detail in subsequent papers.

DISCUSSION

The overall data indicate that in one calendar year 1 of every 11 patients (615 of 6,720) seen in a variety of psychotherapy settings presented an assaultive threat to others in their environment, 126 were physically threatening to the psychotherapist, and 42 actually engaged in assaultive behavior toward the therapist. The 42 patients who assaulted the therapist were distributed among a variety of mental health professionals to the extent that 24% of 101 therapists were attacked during one year by at least 1 patient. Thus attack on the therapist is an infrequent but also inevitable phenomenon that may occur at some time to every therapist. Since one onslaught can end a therapist's career, every therapist should have a working knowledge of a wide variety of techniques to manage assaultive patients that he can put into effect with little delay or deliberation. Although only 24% of the 100 therapists who responded to the question on attack in 1972 were attacked during that year, 74% of the 101 therapists who responded to the question on attack at any time described at least one incident in their professional careers that involved an assaultive patient.

The research team pooled the knowledge that the responding therapists had gained over the years in dealing with violent patients. The eight coping techniques listed above represent this collective experience.

Another way of organizing the eight coping categories is the following: 1) biological—physical and chemical methods of control by others or the self, 2) psychological—verbal methods of control, such as firmness, honesty, and humor, and 3) social—use of family influence, pressure from social institutions, and peer influence.

We have observed that therapists tend to use only one type of technique in coping with assaultive patients. Verbally oriented therapists use verbal techniques, even when physical techniques are clearly indicated, and therapists familiar with physical techniques inappropriately put these into effect when an empathic response would serve better.

Our data indicate that responses to the threat of patient attack are stereotyped and instantaneous; only occasionally are they highly creative. It therefore seems useful for therapists to engage in extensive discussion, rehearsal, and other forms of training so that useful techniques can be employed without delay or

[3]Even if we assume that the 83 nonrespondents and the 1 respondent whose questionnaire was incomplete were not assaulted during 1972, the percent of therapists who reported that they were actually attacked in that year is 12% of the total number of therapists contacted (N=184).

[4]A detailed report of the statistical analysis is available on request from the authors.

deliberation in a crisis situation. If one is aware of other therapists' innovations as possible alternatives, and if the innovations have been practiced, one may have useful additions to a repertoire of therapeutic responses to the assaultive patient. Role-playing techniques, in which the therapist takes the role of an assaultive patient, are one useful way to gain insights into the feelings and impulses of such patients and into the patients' responses to various therapeutic maneuvers.

Nursing Aides and Patient Violence

BY PAULINE LEVY, R.N., AND PETER HARTOCOLLIS, M.D., PH.D.

The authors studied the incidence of violence in a psychiatric unit organized as a therapeutic community whose nursing staff was composed entirely of women in comparison with another unit staffed according to the traditional male and female nursing pattern. The unit staffed by women had no incidents of other-directed violence in the one-year period of the study, but the traditionally staffed unit had 13 violent incidents initiated by 5 patients. The authors state that the expectation of violence among psychiatric patients and the consequent use of male nursing aides to control violence may represent a self-fulfilling prophecy.

CONCERN THAT PSYCHIATRIC PATIENTS may suddenly become assaultive and generally destructive is always present among hospital staff members. This concern and the need to handle violent patients has traditionally and more or less explicitly been the reason for using male nursing aides on the staffs of psychiatric hospitals. Our research suggests that the use of male aides is more likely to lead to violence than prevent it.

BACKGROUND

Two years ago we were asked to reorganize a predischarge transitional ward of a private psychiatric hospital into an autonomous treatment unit. The unit had been operating for several years with a reduced nursing staff, all of whom were women—an unusual arrangement in psychiatric hospitals. We were impressed with the fact that the unit had a very low incidence of violence.

The fact that all of the nursing staff were women was thought to be an outgrowth of the virtual absence of behavior problems on the unit, but we chose to interpret it as the cause rather than the result of the unit's history of nonviolence and to make it part of the new unit's program. Specifically, we hypothesized that violence-prone patients may find female nurses and aides less provocative than male staff and that, conversely, when confronted with threatening patients in the absence of male aides, female staff may be more apt to rely on nonaggressive manners and feminine intuition rather than resort to reactive, policelike methods, which are typical of masculine behavior and values in our culture.

THE PROJECT

The new unit, which had 20 beds and an open-door policy, was located in a private psychiatric hospital that included two other long-term inpatient units of approximately equal size. Our unit was staffed with the following personnel: 3 part-time psychiatrists, 1 resident psychiatrist, 1 full-time and 2 part-time social workers, 1 psychologist, 3 activities therapists, and 15 nurses and nursing aides; all of the nurses and aides were women. The patient population included slightly more women than men, was predominantly young (ranging from 17 to 55 years of age), and represented all diagnostic categories (the predominant diagnosis,

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Ms. Levy is Senior Staff Nurse and Dr. Hartocollis is Director, C.F. Menninger Memorial Hospital, Topeka, Kans. 66601.

however, was borderline personality organization). The average length of patient stay during the one-year study period was six months.

The unit's treatment program was based on the principles of a therapeutic community. Sharing of problems and confrontation by fellow patients and staff members took place in group meetings of patients with staff every day of the week. The meetings could be formal or informal and small or large. Patients elected their own government representatives, who had the right to negotiate issues affecting the patient community in regular meetings with authorities. Responsibility for treatment and the welfare of the community was to be shared by patients as well as staff. This expectation, along with the explicit renunciation of violence, constituted the cardinal value of the unit's philosophy.

The program was designed for direct but voluntary admissions. Preselection was expected to be minimal; the only patients excluded from the unit were those who were currently assaultive. Variables known to contribute to episodes of violence—crowded quarters, shortage of staff, social disorganization, and problems in communication—were carefully monitored and controlled to the best of our ability.

We defined "violence" as behavior that involved aggressive action between 2 or more persons on the unit and produced at least minor physical injury (including scratches and bruises) or destruction of property. Data about violence were obtained from written daily nursing reports. Data from a unit staffed according to the traditional female and male nursing pattern but similar in all other respects were used for control purposes.

FINDINGS

During the one-year period of the study, the incidence of violence in our unit was zero. There were several crises and episodes of disorganization that involved threatening behavior and abusive language, but there were no acts of physical violence on this unit. One young male patient verbally insulted the staff several times but repeatedly assured them and his fellow patients that he would not strike a woman. An older male patient made aggressive gestures toward staff members during a hypomanic episode. He shook his fists, pointed his finger at the staff, and once touched a nurse's nose angrily, but he never hit anyone.

Staff members were impressed with the high degree of self-control patients were able to exercise. Noteworthy, too, is the fact that male patients helped the nursing staff contain the aggression of their fellow patients, providing a source of reassurance for both staff and disturbed patients during stressful times. For example, when a young male patient threatened to strike anyone who tried to prevent him from leaving the unit, other male patients chose to remain in the area until the crisis was resolved. Thus the nursing staff were able to maintain their self-awareness, contain their own fear and anger, and deal with the threatening patient firmly but kindly, managing to prevent him from regressing further into violent action.

In spite of the facts that there was no violence among the patients and no external threat developed, the nurses on the night shift felt vaguely anxious after hours, when no male staff were around and most of the patients were in bed. For example, when a female patient had a male visitor who persisted in prolonging his visit on the unit after midnight, the nursing staff called the night supervisor, who came accompanied by a male aide. Male patients later expressed the wish to be awakened when this sort of incident occurred. On several occasions when this was done, the patients proved very effective in helping nurses deal with problems during late hours, even though their methods did not always satisfy the nurses.

Although there were no episodes of violence against others, self-directed violence did occur a number of times. However, there were no fatal injuries or injuries serious enough to require treatment outside of the unit during the study period. Suicidal threats were fairly frequent.

In contrast, the nursing notes for the control unit showed 13 instances of assaultive behavior initiated by 5 different patients.

No systematic count of episodes of violence was carried out in the other long-term treatment units of the hospital, which continued to use the traditional female and male nursing staff pattern, but a sampling of the records of these units and anecdotal data indicate that over the one-year study period they experienced a proportionally greater amount of violence. Whether the incidence of self-directed violence or threats of such violence was different in other sections was not investigated.

DISCUSSION

Even though the incidence of violence may not be as great in psychiatric hospitals as it is in other total-care institutions, the idea that patients in a psychiatric hospital may suddenly become assaultive is prevalent, not only among laymen but also among psychiatric personnel—especially nurses and nursing aides (1). The expectation of violence and generally destructive behavior may constitute a self-fulfilling prophecy that needs to be recognized and treated as a transference or countertransference problem. When nursing staff fear that patients under their care may become violent, the probability is that they are concerned about their own propensity for violence and the fear that they may not be able to contain it if sufficiently provoked. Feelings of inadequacy concerning the staff's ability to handle a difficult situation, when accompanied by frustration and anger, may scare a disturbed patient to the point of driving him to violence (2).

Spiegel (3) pointed out that confrontation is an effective means of resolving group conflict and promoting

social change but that it carries with it "the strong possibility of physical violence." Confrontation is the technique most widely used to resolve conflict and to effect change in a therapeutic community. However, for confrontation to become dangerous, there must be an intent and a reciprocal expectation of violence, based on the belief that for confrontation to be effective there should be violence or the option to do violence. When a male aide is used as an instrument of confrontation, the probability of violence becomes greatly enhanced because the male aide's formal or informal role as masculine authority is based on the intent to do violence. This intent is potentiated by female nursing personnel who expect the male aide to confront troublesome patients for them.

Storr (4) found that male aggression tends to occur spontaneously in a wide array of conditions, such as rivalry, territoriality, and display, but that aggression in females is fully aroused only or mainly in response to a threat that involves their young. Bigelow (5) noted that one of the causes of severe aggression in animals is "the crowding of strangers, especially near such valued resources as food or mates."

Crowded conditions in a hospital, which are known to cause violent episodes and regression of all sorts, mean not only deprivation of space and privacy but also shortage of personnel in the sense that relatively few patients can get the attention they need from very busy staff members (6). Patients who cannot or are not allowed to use their own potential for mutual assistance and sharing of responsibility tend to compete for the attention of nurses and aides, whom they perceive as "valued resources" to obtain aggressively or, if denied, to destroy in frustration.

In our experience, the possibility of violence threatened the nursing staff most when the structure of the patient-staff community was weak. When the ability of the community members to support each other or, more generally, when its ability to adhere by the common rules and values (beginning with the renunciation of violence) were not trusted, fear and unrest prevailed. External controls were then desired, and, as a crisis developed, they were sought in the form of phone calls to an authority outside of the unit and in the importation of male aides. The night personnel were more apt to mistrust the community's controls and often failed to make full use of the community because they had the least exposure to its working sessions. All of the regular community meetings took place during the day. Nurses and some patients longed for the presence of male aides, especially after dark.

In nonhuman primate social groups as well as in primitive human societies, order is maintained through the power of males (5). Likewise, in mental hospitals male aides have been traditionally employed to contain aggressive patients or to enforce unpopular rules by a show of sheer muscular force. In the case of night personnel, there is also the real or imaginary fear of intruders. Perhaps a metaphor, or dynamic, can be applied to nurses—as wives who wish for their husbands to come home at night. The patients' wish for a male aide in the evening may express a parallel dynamic—the wish for a father to come back home when a day of work is over. The wish for the presence of male nursing staff, especially at night when other male staff are not around, may also indicate concern about the sexual feelings of the female nursing staff or of the patients toward these women and the need to safeguard the nurses' professional roles as substitute mothers.

CONCLUSIONS

We believe that the exclusive use of female aides may keep the incidence of other-directed violence in a psychiatric hospital to a minimum. We also feel that the absence of male aides should not necessarily hamper the treatment process. The wish of some female nurses and aides to have the benefit of the presence of male aides seems to us less related to good treatment and more related to professional, cultural, or dynamic factors that could interfere with treatment.

A Violence Clinic: Three Years' Experience

BY JOHN R. LION, M.D., DENIS J. MADDEN, PH.D., AND RUSSELL L. CHRISTOPHER, M.D.

The authors describe a clinical facility established for the neuropsychiatric treatment of individuals with a variety of psychopathological disorders where the common management problem is one of aggressive behavior. The authors present case vignettes to illustrate the clinic's consultation with mental health workers about the management of violent patients, countertransference problems, ward problems, the role of organic factors, medication, and prediction of violence. They urge that the subject of violence be included in the psychiatrist's training.

IN THIS PAPER we will discuss the consultation, teaching, and research functions of a specialized clinical service within the psychiatric unit of a general hospital. The clinic, begun as an extension of our interest in clinical problems of aggression (1–4), sees a range of patients with psychopathology including severe characterological disturbances, adjustment reactions, toxic and functional psychoses, and organic brain syndromes. In all of these disorders, aggressive behavior is the common management problem. Our experience to date with more than 400 patients roughly parallels statistical data and profiles previously described (5, 6).

A combined psychological and neurological approach to the problem of aggression has involved a study of psychodynamic factors as well as brain dysfunction, since we believe that aggression is a phenomenon closely linked to impulsivity (7) and, as such, is a behavior in which organic factors may contribute to the poor control of aggressive urges and the paroxysmal expression of hostile outbursts. Our patients are treated with psychotherapy and the adjunctive use of medications.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

At the time this work was done the authors were with the Department of Psychiatry, Institute of Psychiatry and Human Behavior, University of Maryland School of Medicine, Baltimore, Md. 21201, where Dr. Lion is Associate Professor and Director, Clinical Research Program for Violent Behavior; Dr. Madden is Clinical Assistant Professor and Associate Director of the Program; and Dr. Christopher was Chief Resident. Dr. Christopher is currently Staff Psychiatrist, Neuropsychiatric Medical Group, Huntington Beach, Calif.

This work was supported by the Foundation for Clinical Research in Psychiatry, Inc., Baltimore, Md.

As the clinic has become a recognized entity, we have found ourselves involved in the following tasks.

CONSULTATION

Social and medical agencies frequently request consultation regarding the management of a violent patient. In such instances personnel have grappled with the problem of treatment or have questions regarding the diagnosis and the proper use of medications. In other instances staff difficulties or therapist countertransference reactions become apparent.

Vignette 1. A borderline psychotic woman was seen at a local hospital because of repeated assaultive and self-mutilative behavior. She had attacked members of the staff and had swallowed objects, necessitating five laparotomies. She was isolated and identified as a notorious patient among the several thousand patients of the hospital. In discussion, two elements of therapeutic importance emerged. The staff's anxiety in dealing with the patient had magnified her dangerousness to the point where avoidance was seen as preferable to confrontation, which might evoke some aggression. The avoidance minimized therapeutic interaction. In addition, the patient received only moderate amounts of medication and a pharmacological repertoire had not been tried in any systematic fashion. Discussion of both issues with staff let to improved patient management with a significantly reduced number of aggressive outbursts.

This case illustrates several issues. First, staff reactions to a patient can be a strong force in alienating the patient and eventually worsening his psychosis or behavior by virtue of the induced sensory isolation. Anger that is displaced by staff onto the patient can intensify such punitive seclusion as personnel find it difficult to ventilate their helplessness about a difficult patient (4). A second issue was the inadequate use of medication. The aim of treating a violent patient with medication is not to render him helpless and inert but to allow him to effectively modulate his own aggressiveness. To this extent, however, medication must be used in a forthright and systematic manner. We have been active in formulating guidelines for the use of specific drugs in the control of violent patients (8).

The next case is a more social one, involving not a particular patient but an entire hospital.

Vignette 2. Distant consultation was requested in a northeastern state hospital due to what was labeled an "out-

break of violence" among the patients. Upon their arrival, clinic personnel discovered that several members of the staff had been indicted for physical abuse of patients. Inspection of the situation revealed a paucity of psychiatrists and the recent arrival of a patients' legal rights advocate. Thus there was not enough staff to properly manage difficult patients, and because of the excessive concern about the rights of patients, any necessary physical restraint of an aggressive patient was perceived as a possible legal transgression.

This case illustrates the complexity of the problem of violence "epidemics," a phenomenon with which we have now gained some experience. Generally, the issue is one of morale that is passed down to patients, or it may be one of staff conflicts similarly handed down. Epidemics reflect staff splitting and dissension, and such phenomena are seen on a smaller scale on ward settings as well. Consultation in such matters is a delicate operation since the issue of staff mismanagement may well arise and feelings of defensiveness are thus heightened. At one recent consultation to a school for delinquent adolescents, the staff stated that "a problem existed with regard to the acting out of the patients." Such euphemistic phrases obscure the true level of violence and yet at the same time reveal the staff's feelings about violence and their own inability to express violent fantasies and urges.

From time to time we have been asked to see rather esoteric cases of violence. Some of these cases are forensic, and others involve social and medical policy issues.

Vignette 3. A mentally retarded man was hospitalized with a request for psychosurgery because of intractable violent behavior and self-mutilation. The patient was kept physically restrained or secluded almost continuously. He had enucleated one eye and disjointed a nasal septum. The possibility of stereotactic amygdalectomy was discussed, but it was apparent that a full medical regimen had not been tried and no justification for any surgical procedure existed since the patient was not epileptic. However, it was recognized that he was probably doomed to remain incarcerated unless an effective medical regimen was used.

Recent social policy regarding psychosurgery for aggressive patients has justifiably raised doubts about the ethics and efficacy of such procedures, and the entire matter has been reviewed by government agencies (9, 10). While it appears that there may be a moratorium on psychosurgical research, it must also be recognized that there does exist a rare class of patients so hampered by violence as to make their existence quite intolerable for themselves and others unless drastic action is taken. In the case just described, we were not convinced that a full medical armamentarium had been tried and made academic suggestions to the referring hospital. Their reply, understandably, was that it was simple for us to suggest higher dosages of chlorpromazine since we did not have to care for the patient. Other patients we have seen in prison settings have presented similar dilemmas. The following case illustrates a social policy issue of a different nature.

Vignette 4. A 25-year-old surgical resident was referred because he had been assaultive to a patient on the geriatric ward. The physician had experienced much helplessness as a child and reacted inappropriately to an infirm and elderly patient who tended to harass him and make unreasonable medical demands. The dynamics of the case were clear to the interviewer, who felt that psychotherapy was imperative. The resident refused such treatment, and his superiors then insisted that he undertake such therapy or leave the program.

This difficult consultation raised the issue of confidentiality and coercive treatment. The phenomenon of medical staff reacting inappropriately toward older, helpless patients or toward children is not uncommon and can be seen in child abusers as well. We have seen several physicians and policemen with tendencies toward temper outbursts of sufficient severity to bring them to the attention of superiors. The common dynamics in these cases were helplessness and strong reaction formations against passivity and weakness. The appearance of disorders of aggression in professionals is in contrast to the usual finding that aggressive patients come from lower socioeconomic strata. We believe that such a skew reflects in part society's handling of aggressive individuals, whereby those middle- and upper-class patients who become violent are treated differently within the legal and medical systems.

TEACHING

Within the medical school, the clinic serves to instruct students and residents in the evaluation and management of violent patients. For some time it has been our feeling that patients with propensities toward violence are shunned by a profession that is more in harmony with the introjection of aggressive urges (6). This is particularly true of patients who suffer from personality disorders and who may have criminal histories. Such individuals are perceived as material for courts and prisons, rather than psychiatry. Clinical decisions are of course necessary to distinguish the treatable from the nontreatable and purely manipulative individuals who wish psychiatric help to avoid court action, for example.

Yet in the history of our discipline, knowledge of aggression has often been derived indirectly through the study of normal aggressive drives in nonaggressive patients, such as depressed individuals or those with psychosomatic diseases (7). We submit that to learn about aggression and the dynamics of that drive, one must study patients whose primary problems are with aggression. Too often, the aggressive patient is still handled dispositionally and shunted to end-stage facilities such as state hospitals.

Vignette 5. A patient was hospitalized because of temper problems at work and home. He presented a hostile facade with a belligerent, provocative stance. The staff came to fear

him and expected him to live up to their expectations, that is, to explode with anger in group therapy or on the ward. In time, with supervision, the staff was able to see that the patient was actually an individual with a fragile sense of self-esteem, which he could acknowledge. Further, his outbursts were not random or instantly paroxysmal but came as the result of a perceived insult, and the patient could be taught to recognize premonitory signs and symptoms indicative of an incipient outburst. Thus he was able to verbalize his anger rather than handle it behaviorally.

Examples such as this illustrate the dynamics in patients with severe characterological disorders, who are prone to handle affective issues behaviorally and create disturbances within the milieu (11).

Management problems exist in individual therapy also.

Vignette 6. A psychiatrist phoned to seek advice regarding the handling of a paranoid schizophrenic patient. The patient had made homicidal threats on the telephone, and the therapist had dealt with these threats by not responding and hanging up. His anxiety mounted as the threats continued. In discussion, it became evident that the patient had made similar joking threats in therapy as intimacy progressed, and the therapist had casually dismissed such threats and gestures. The therapist was encouraged to confront the patient and discuss what appeared to be unresolved transference and countertransference issues.

This is a frightening example that dealt in large measure with a problem of denial, a defense we have often noted in the therapy of such patients. Homicidal threats often bespeak underlying nurturant needs that are frustrated on some level, and such threats demand confrontation and clarification. Residents often require guidance in the therapy of patients whom they come to perceive as dangerous; in such instances reality issues must again be separated from countertransference problems (12).

Of particular interest is the need to teach students to accurately assess violent propensities. This is done by inquiry into the patient's past use of violence, criminal history, driving history, ownership of weapons, and by other questions that can evoke anxiety. Interviews with and treatment of provocative victims are mandatory in the therapy of violent patients once a pathological relationship has been established (6). Awareness of organic factors is necessary in the management of certain violence-prone individuals who manifest some degree of brain dysfunction. The dysfunction can range from rare psychomotor epilepsy to more subtle states of brain dysfunction detectable by careful cortical function examination, including psychological, neurological, and EEG testing (11).

RESEARCH

We have been active in the psychopharmacological control of aggression (13). To summarize briefly, there is no one drug for the treatment of aggression since aggression is a manifestation of a variety of psychopathological conditions. However, once an etiology is established, one class of drugs may be more useful than another. For example, anticonvulsants or benzodiazepines with anticonvulsant properties may aid in the treatment of explosive personalities of patients prone to ictal forms of aggression; lithium may be useful in treating aggressive patients with underlying affective disorders when the manifestation of the affective disorder is psychomotor excitation rather than true mood swings.

In addition to pharmacological work, we have been interested in psychotherapeutic techniques that involve an elaboration of fantasy in individuals who appear to have a poor ability to anticipate the consequences of their acts. We are also interested in teaching patients, particularly those with personality disorders of paranoid, explosive, passive-aggressive, or antisocial types, to recognize their affective states and describe them verbally, thus making their feelings amenable to communication (14). This is done in individual and group therapy (15).

COMMENT

Our clinic is no more than a group of individuals interested in problems of aggression. We do not advocate the establishment of violence clinics but do urge that the training of psychiatrists include education in the topic of violence. If we are to understand aggression to the same degree as we hope to conceptually understand and therapeutically deal with depression, we must work with and learn from patients who are aggressive.

Journal Policy on Multiple Authorship

It has come to our attention that there has been some misunderstanding regarding the *Journal*'s policy on polyauthorship. The number of authors listed on a paper is not a factor in the review and acceptance/rejection procedure. However, once a decision has been made to publish a paper, we do apply *Journal* policy regarding the number of authors in the by-line: only principal researchers and writers of articles are listed in the by-line; collaborators who have provided technical and other assistance are acknowledged in a footnote. In papers that list more than 4 people as principal authors, we query the first author to verify that those individuals were substantial contributors to the research or ideas reported. Since certain types of psychiatric research may require multiple workers, we will of course include all of the names in these cases.

EDITORIAL

Rape: "The Ultimate Violation of the Self"

THE PUBLICATION IN this issue of the *Journal* of four articles with an empathic focus on rape victims marks a sharp departure from much of the previous medical literature on the subject. Most striking has been the absence, until recently, of any significant literature about the victim other than that limited to medicolegal concerns, although a variety of articles have focused on the need to understand and rehabilitate the rapist. The reader was provided with a mass of instruction designed for the medicolegal protection of the examining physician rather than the victim. Further, the assumption permeating many of the articles was that the victim may have provoked the crime: had she been drinking, was she seductive, sexually active, did she know the assailant? Similar attitudes prevail in the criminal justice system, with its stringent corroboration requirements in rape cases; such corroboration has been supported because "We know from the lessons of the past that all too frequently such complainants have an urge to fantasize or even a motive to fabricate . . ." (1).

The theme of woman as liar pervades our constructs about rape victims and underlies the assumption that women often make false charges of rape against men, even men they do not know. While law enforcement personnel are aware that false charges of crime occur, it is only in rape cases that it is assumed that the usual safeguards in the system cannot protect the innocent from a lying witness (1, 2). In robbery, for example, it is understood that property was taken from the victim without his/her consent, and there is no need to prove that fear of death or grave bodily harm was at issue. The law, then, grants more protection to property than to the person, especially if the person is female.

Both medical and criminal justice institutions reflect the same mythology that society perpetuates about rape. The abundant mythology suggests that prior sexual experience on the part of an unmarried victim is reasonable evidence of "provocation"; women ask for rape by seductive behavior and dress; "nice girls don't get raped and bad girls shouldn't complain" (1); and women can't be raped unless they want to to be, corollary being that women actually enjoy rape. The victim is thus perceived as a responsible and not an innocent party to the crime.

The act of reporting a rape initiates a complex process. The victim is confronted with the usual institutional patterns of the hospital and criminal justice system, which at best are experienced as confusing and alien. She presents herself to these authorities at a time of crisis that differs from other crises in that her usual support system is more likely to be disrupted. Families, friends, and lovers, because of their own perceptions about rape, may desert and further isolate her. Moreover, the crisis is never limited to one's person since the victim, by the act of reporting, becomes public property and is at the mercy of the hospital, police, courts, media, and community opinion.

Rape is "the ultimate violation of the self" (3) short of homicide and is best understood in the context of a crime against the person and not against the hymen. Rape is an act of violence and humiliation in which the victim experiences overwhelming fear for her very existence as well as a profound sense of powerlessness and helplessness which few other events in one's life can parallel. The victim

needs empathy and safety and a sense of control over what has happened to her and what will happen in her encounters with hospital and law enforcement. In the absence of sensitivity to these needs, the experience of reporting becomes another assault.

It is not surprising that the four papers on rape in this issue were written by women. Recent attitudinal shifts have been largely due to the initiative taken by the countless numbers of women who have begun to sensitize our medical, social, and legal institutions about the extent to which cultural biases have determined the maltreatment of the victim. Deena Metzger's paper (4) stands as a deeply moving account of the meaning of the personal violation which defines the rape experience. Her concept of rape as a "ritual of power" is supported by a growing body of information (5, 6) about the social context in which rape occurs; the same concept is presented with eloquence by Susan Brownmiller (6), who suggests that rape has the same meaning for women as did lynching for blacks: "That *some* men rape provides a sufficient threat to keep all women in a constant state of intimidation, forever conscious of the knowledge that the biological tool must be held in awe for it may turn to weapon with sudden swiftness born of harmful intent."

Innovative and empathic services to victims will serve as a deterrent to the crime by facilitating reporting of the crime and thereby the apprehension and prosecution of the assailants. Ultimately, however, the elimination of rape demands a massive restructuring of social values to include a reconsideration of the relations between the sexes. Only when the sex roles of both men and women are defined by individual needs and talents rather than by stereotypic expectations based on sex and power motives will there be an end to rape.

ELAINE HILBERMAN, M.D.

Dr. Hilberman is Assistant Professor of Psychiatry, School of Medicine, University of North Carolina at Chapel Hill.

BRIEF COMMUNICATIONS

Reduced Platelet Monoamine Oxidase Activity in a Subgroup of Schizophrenic Patients

BY JOSEPH J. SCHILDKRAUT, M.D., JAMES M. HERZOG, M.D., PAUL J. ORSULAK, PH.D., STUART E. EDELMAN, M.D., HARVEY M. SHEIN, M.D., AND SHERVERTH H. FRAZIER, M.D.

Platelet monoamine oxidase (MAO) activity was significantly lower than control values in a subgroup of 16 schizophrenic patients (most of whom were paranoid) characterized by the presence of auditory hallucinations and delusions. Platelet MAO activity was not reduced in 16 other schizophrenic patients without auditory hallucinations. This finding suggests that reduced platelet MAO activity is not found in all schizophrenic patients but tends to occur in a clinically identifiable subgroup.

SEVERAL STUDIES have reported that some patients with schizophrenic disorders have lower platelet monoamine oxidase (MAO) activity than controls (1–4), but this has not been observed in other studies (5–7). It has been noted that reduced platelet MAO activity occurs more commonly in chronic than in acute schizophrenic disorders (8). However, other clinical characteristics that may be associated with reduced platelet MAO activity in schizophrenic patients have not yet been demonstrated.

In a pilot study of platelet MAO activity in schizophrenic patients hospitalized at the Massachusetts Mental Health Center or the McLean Hospital, we noted that reduced platelet MAO activity regularly occurred in a subgroup of schizophrenic patients (most of whom were paranoid) with auditory hallucinations and delusions. In order to confirm this initial observation, we examined platelet MAO activity in a subsequent series of patients hospitalized at the Massachusetts Mental Health Center with the diagnosis of schizophrenia. In both of these studies the clinical diagnosis was made in accordance with the *Diagnostic and Statistical Manual of Mental Disorders* of the American Psychiatric Association (9).

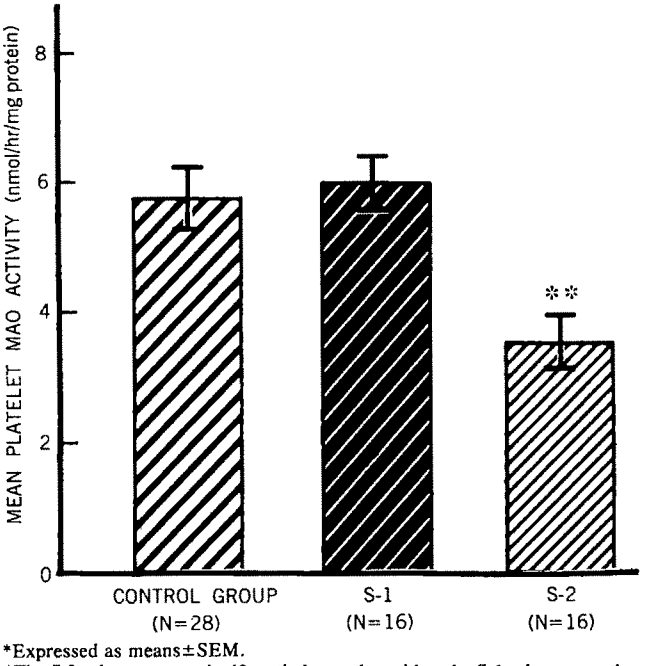
METHOD

The medical records of the schizophrenic patients were reviewed in detail by a psychiatrist blind to the biochemical data. The patients were then categorized according to whether they had a record of both auditory hallucinations and delusions. The subgroup of patients with both documented auditory hallucinations and delusions (N=16) was designated S-2, whereas the remaining subgroup of schizophrenic patients (N=16) was designated S-1. Each subgroup contained 8 men and 8 women. Most of the male patients and half of the female patients in the S-2 subgroup had delusions or auditory hallucinations that were of a persecutory or accusatory nature and thus were designated paranoid.

Platelets were isolated from blood routinely obtained at the time of hospital admission by a modifi-

Presented at the New Research Session at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Drs. Schildkraut and Frazier are Professors of Psychiatry, Drs. Herzog and Edelman are Clinical Instructors in Psychiatry, and Dr. Orsulak is Associate in Psychiatry, Harvard Medical School, Boston, Mass. Dr. Schildkraut is also Director and Dr. Orsulak is Associate Director, Neuropsychopharmacology Laboratory, Massachusetts Mental Health Center, 74 Fenwood Rd., Boston, Mass. 02115. Dr. Frazier is also Psychiatrist-in-Chief, McLean Hospital. Dr. Shein, until his death on July 18, 1974, was Associate Professor of Psychiatry, Harvard Medical School, and Psychiatrist, McLean Hospital.



This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-15413 from the National Institute of Mental Health and by a grant from the Benevolent Foundation of Scottish Rite Freemasonry, Northern Jurisdiction, U.S.A.

The author wish to thank Mr. Vincent DaForno for his technical assistance.

cation of the procedure of Murphy and associates (10). MAO activity was determined by measuring the deamination of ^{14}C-tryptamine bissuccinate and was expressed as nanomoles of tryptamine deaminated per hour per milligram of platelet protein (11). When this method was used in a series of 26 subjects on whom 3 or more consecutive daily samples were examined, the intrasubject coefficient of variation was 10%±1.5% (mean±SEM). Similarly, the average coefficient of variation for samples of pooled platelets analyzed repeatedly over a period of 4 months was approximately 10%.

Patients with histories of alcoholism were excluded from this study since we and others have observed reduced platelet MAO activity in some patients with alcoholism (12, 13). Patients were also excluded if there was a prominent affective disturbance (mania or depression) or evidence of any major neurological or medical illness. In order to control for the effects of advancing age on platelet MAO activity (14), patients over 45 years old were not studied. We also studied platelet MAO activity in an age- and sex-matched control group consisting of 28 staff members of the Massachusetts Mental Health Center.

FIGURE 1
Platelet MAO Activity* in Two Subgroups of Schizophrenic Patients

*Expressed as means±SEM.
**The S-2 subgroup was significantly lower than either the S-1 subgroup or the control group ($p<.001$, t test).

RESULTS

As shown in figure 1, patients with a diagnosis of schizophrenia but no documentation of auditory hallucinations and delusions (the S-1 subgroup) had platelet MAO activity that was very similar to that of the control group. In contrast, schizophrenic patients with both auditory hallucinations and delusions (the S-2 subgroup) had significantly lower platelet MAO activity ($p<.001$) There was very little overlap in the individual values of MAO activity in patients in the two schizophrenic subgroups.

The S-1 and S-2 subgroups did not differ in age or sex distribution, and MAO activity was not correlated with antipsychotic drug dosage. Moreover, MAO activity was not related to the number of previous hospitalizations or to the length of time since the first documented hospital admission, thus suggesting that the reduced platelet MAO activity in the S-2 subgroup was not merely related to chronicity of illness. Within the S-2 subgroup, the lowest individual values of platelet MAO activity were observed in patients who were paranoid, as suggested by observations made in our earlier pilot study.

DISCUSSION

Our findings indicate that reduced platelet MAO activity is not found in all schizophrenic patients; rather, it tends to occur in a clinically identifiable subgroup. The original blind selection of the S-2 subgroup was made on the basis of a history of both auditory hallucinations and delusions. However, further examination of the data suggested that the primary discriminating symptom may have been the presence of auditory hallucinations since none of the patients in the S-1 subgroup were found to have auditory hallucinations, although many had delusions. Thus it is possible that our S-2 subgroup may correspond to schizophrenic subtypes identified in other studies on the basis of auditory hallucinations (15).

A prospective study is now under way to determine whether the presence of auditory hallucinations (particularly in conjunction with paranoid features) may be a sufficient criterion for identifying a subgroup of schizophrenic patients with reduced platelet MAO activity. We also hope to clarify the relationship of the subgroup of schizophrenic disorders with reduced platelet MAO activity to paranoid schizophrenia.

The 24-Hour Lithium Level as a Prognosticator of Dosage Requirements: A 2-Year Follow-Up Study

BY THOMAS B. COOPER, M.A., AND GEORGE M. SIMPSON, M.D.

The authors have previously described a technique whereby individual lithium dosage requirements can be predicted from 24-hour blood samples. Further experience over a 2-year period has shown the predictions to be reproducible over time. A micromethod for lithium determination is described, as are several cases in which aberrant results were found to indicate inadequate laboratory techniques or patients' failure to take medication. Because the technique reveals immediately those patients at the extremes of dosage ranges, toxicity and the need for frequent sampling can be avoided.

APPROXIMATELY two years ago, we wrote two papers on the kinetic analysis of data collected from patients given a single 600-mg dose of lithium carbonate. In the first paper (1), we were able to show that we could predict, with acceptable clinical accuracy, the individual dosage requirements of each patient. In the second paper (2), we demonstrated that each patient's dosage could be ascertained from a single blood sample collected 24 hours after a 600-mg dose of lithium carbonate. A correlation of .97 (N=19) was obtained when the 24-hour blood level was compared with the steady state level after a fixed dosage regimen. The predicted individual dosage requirements, derived from the empirical data described in the previously mentioned papers (see table 1), have not required alteration after experience with more than 100 patients' predictions. Thus, from a single blood sample taken 24 hours after a 600-mg dose of lithium, it is possible to predict an individual dosage regimen to ensure that a patient will be within the therapeutic range.[1]

During the intervening years, our experience has shown that in patients who ingested the medication and from whom blood samples were collected 24 hours later, the prediction always resulted in a steady state lithium level of 0.6–1.2 mEq/liter. The steady state level is that found in blood collected immediately before the next dose of medication is due; this sample approximates the lowest level to be found during the continuous ingestion of the medication on a fixed schedule.

The convenience of the technique is best seen in an outpatient situation, wherein the patient is given 600

The authors are with the Rockland Research Institute, Orangeburg, N.Y. 10962, where Mr. Cooper is Chief Investigator and Dr. Simpson is Principal Research Psychiatrist.

[1]Since this paper was accepted for publication, Seifert and associates (3) have confirmed this prediction technique using a long-acting form of lithium.

mg of lithium carbonate by the clinician or to take at a later time so that attendance at the laboratory or physician's office will be within normal working hours. The results of the blood analysis should be available on the same day and the patient should then be started on the predicted dosage schedule. When laboratory results are not quickly obtainable, the clinician can start the patient on a schedule of medication immediately after the 24-hour blood sample has been collected and the dosage can be adjusted if necessary when the laboratory data are available.

During the years the technique has been in use, there have been several patients who have had 24-hour blood levels determined and who received lithium but stopped taking it for a variety of reasons. On retesting, their 24-hour blood levels were found to indicate the same dosage requirements as were determined previously. In a study of the effects of lithium on tardive dyskinesia (4), 600-mg doses of lithium carbonate were given and 24-hour blood samples were collected on 3 separate occasions, each dose being separated by a drug-free interval of at least 1 week. As table 2 indicates, the level is highly reproducible and the predictions are therefore equally reproducible. In all cases, the patient achieved satisfactory blood levels on the predicted dosage.

Schou (5) reported that renal clearance of lithium was decreased in older patients. Examination of the predictions obtained for the aforementioned study of lithium and tardive dyskinesia in older patients (4) (age range 57–82 years, mean age=72) indicated that all but 2 patients required 300 mg three times a day or less to achieve a level of 0.6–1.2 mEq/liter. This confirms Schou's original observation.

TABLE 1
Dosages Required to Achieve a Serum Lithium Level of 0.6–1.2 mEq/liter*

24-Hour Serum Level After Single Loading Dose (mEq/liter)	Dosage**
Less than .05	1200 mg three times a day
.05–.09	900 mg three times a day
.10–.14	600 mg three times a day
.15–.19	300 mg four times a day
.20–.23	300 mg three times a day
.24–.30	300 mg twice a day
More than .30	300 mg twice a day***

*Reprinted from Cooper and associates (2).
**The regimen selected minimizes fluctuation in the plasma level while maintaining a schedule the patient can adhere to. Variation in this regimen can be made at the choice of the clinician, but the total daily dose must remain the same. All steady state values are collected just before the next medication is to be taken.
***Use extreme caution.

MICROMETHOD FOR LITHIUM DETERMINATION

With the greater likelihood of "difficult veins" and the general frailty of a geriatric population, as well as the current interest in the use of lithium in children, a true micromethod for the determination of lithium seemed esssential. We therefore developed a suitable method, requiring 50 μl of plasma, wherein blood can be collected by finger prick into a heparinized microhematocrit tube (technical details have been published elsewhere [6]). For convenience, the technique is given in abbreviated form in appendix 1. The precision and accuracy of the micromethod were not significantly different from our routine macromethod, which has a coefficient of variation of 1.5%. Therefore, because of the high correlation between the methods, they can be used interchangeably to predict dosage requirements or to ascertain the steady state plasma level. In our own hospitals, nursing staff collect blood via finger prick and then place the hematocrit tubes in a clean, stoppered, labeled tube for transportation to the laboratory. An additional benefit is that the red cell lithium: plasma lithium ratio can be determined. This measure has been claimed to be increased in manic-depressive psychosis and to have importance in patients who have toxic symptoms without abnormal plasma levels (7–9). (We have never observed a change in the ratio in patients demonstrating this phenomenon.) The ratio has also been claimed to be of value in selecting a subgroup of depressed patients who may respond to lithium as an antidepressant (10).

PREREQUISITES FOR PREDICTION

Clearly, the prediction technique depends upon the following: 1) the patient ingesting all of the medication, 2) the blood sample being collected at the correct time (less than 60 minutes before the next scheduled dose), 3) the laboratory being capable of accurate, reproduc-

ible analysis, and 4) the clinician understanding the limitations of any predictive technique.

Blackwell (11) has written an excellent mini-review and described a study determining the failure rate in patients taking any kind of medication. In our own experience with lithium and other psychotropic drugs, there have been patients whom we trusted and who we felt confident were taking their medication—but hard laboratory data revealed that they were not. Thus, we have seen unmeasurable serum lithium levels 2 hours after a routine 600-mg dose of lithium, but a level of 0.6 when the medication was dissolved in orange juice and the patient was observed for the full 2-hour period. These patients have admitted hiding the medication and taking it later, discarding it, or giving it to other patients; some even have the ability to hold medication in the nasopharyngeal area to avoid detection. One outpatient who consistently had steady state levels of lithium within the therapeutic range admitted that she took two capsules (600 mg total) 2 hours before visiting the laboratory each month, but that was the only time she took the medication. These examples are cited to draw attention to the fact that if an aberrant result is found, the patient as well as the laboratory technique should be suspected; one may thus identify patients who will require careful monitoring to ascertain that they are taking their medication.

The determination of serum lithium levels is not a difficult laboratory procedure, and it is not unreasonable to require accuracy to the second decimal place. Our general experience with this technique when used in other units by other workers has been good (i.e., they found the prediction technique useful); however, the exceptions have, upon investigation, yielded somewhat startling findings.

REASONS FOR ABERRANT RESULTS

Several investigators informed us that if they split samples and send them to the same laboratory as different samples, the results can vary by as much as 0.5 mEq/liter. Recently, a resident in our psychiatric training program who had used this technique transferred to another hospital and found a laboratory result of 0.86 mEq/liter at 24 hours for the first patient given 600 mg of lithium. After waiting for 3 days, she repeated the procedure and a level of 0.39 mEq/liter was reported. Table 2 shows that this kind of variation is impossible unless the patient took extra lithium the first time or the laboratory was incapable of measuring lithium levels. This experience makes it clear that laboratory accuracy is a prerequisite for this technique. It may be necessary for the physician to make the pathologist and/or clinical chemist aware of the importance of this particular sample so that additional care will be exercised. This, however, is a poor substitute for a well-controlled laboratory procedure.

Early in our experience, one clinician said that he found our predictions consistently high and that he always used lower dosages; upon further inquiry it turned out that this physician did not want his patients to have serum lithium levels above 0.9 mEq/liter; he preferred a range of 0.6–0.8 mEq/liter. The technique as it currently stands cannot predict such a narrow range, but we find that even the physician who demands the narrowest range can still obtain valuable information, in that he can at least know that a patient will require very little (300 mg twice a day or less) or a great deal of medication (900 mg three times a day or more) to achieve the generally accepted range (0.6–1.2 mEq/liter) and can tailor his own prescribing with this in mind.

In another case a clinician collected the blood 2 hours after the patient ingested the medication rather than immediately before the next dose. Clearly, this will produce higher levels and the erroneous conclusion that the technique is invalid.

DISCUSSION

We should emphasize that this technique predicts individual dosage requirements with acceptable clinical accuracy; it does not, however, predict subsequent changes in renal clearance or other physiological changes. We have been asked about this on occasion, and there is no way that we can predict this situation—nor, as far as we know, can anyone else. It is clear that a patient who was found to require 600 mg three times a day to achieve steady state levels might well become toxic on this dosage if renal clearance diminishes during the therapy. The data on the needs of the elderly population studied (see table 2) clearly suggest that the amount of lithium required decreases over many years.

Since the prediction technique has become routine, we have found that less frequent blood sampling has been required during the initial medication period and that medication changes are rarely needed. Subsequent monthly and, later, quarterly or semiannual blood determinations are still required with or without the prediction technique.

Blood levels can vary widely among patients. We have found patients who have required less than 300 mg twice a day or more than 3 g a day to achieve steady state levels within the therapeutic range. One of our patients requires 150 mg (1/2 tablet) a day and on this regimen has a steady state level of approximately 0.7 mEq/liter. The majority of the clinicians who are using the technique have found it to be of value. We feel that the exceptions are idiosyncratic, e.g., a clinician who feels there is no need for such a method because the manic episode is controlled by neuroleptics, while prophylactic lithium does not require rapid achievement of a therapeutic level. Our own opinion is that because the technique is simple and indicates immediately those patients at the extremes of the dosage range, toxicity and the need for frequent blood sampling can be avoided.

APPENDIX I
Micromethod for Serum Lithium Determination

The finger is cleansed and the standard finger prick method is used. The blood is collected by means of heparinized capillary microhematocrit tubes, which are centrifuged so that a clear plasma layer is obtained. The plasma is withdrawn (50 μl) by means of a Hamilton Syringer number 70001-N (sufficient plasma can be obtained from two capillaries) and placed in a small vial containing 1 ml of deionized water.

Aqueous standards containing 0.5, 1.0, 1.5, and 2.0 mEq/liter of lithium are prepared fresh from a concentrated stock solution each day. These standards are further diluted with deionized water (1:20), and to 1 ml of each of these diluted standards is added 50 μl of lithium-free plasma or 50 μl of 6% dextran solution. These solutions are then aspirated directly into a Perkin-Elmer Model 303 automatic absorption spectrophotometer with a DCR-1 attachment (or comparable instrumentation) and four readings are obtained from the equipment (operating under continuous mode). The last three readings are recorded and the mean is determined. The equipment is calibrated before the tests to read out directly in milliequivalents by aspiring a larger volume of the 2.0 mEq/liter standard, similarly diluted. Readings are obtained until the equipment stability and calibration are ascertained.

Our standard macromethod uses 0.5 ml of serum plus 2 ml of water and standards similarly diluted with either serum or 6% dextran. The coefficient of variation for this method is 1.5%.

Extrapyramidal Side Effects in Lithium Maintenance Therapy

BY MARC H. BRANCHEY, M.D., JESS CHARLES, M.D., AND GEORGE M. SIMPSON, M.D.

The authors neurologically examined 36 patients who had been maintained on lithium therapy for periods ranging from 6 months to 7 years to determine the presence of parkinson-like side effects. Only a few patients demonstrated rigidity, including cogwheel rigidity, and this was at a low level of severity. These results do not support the previously reported frequent occurrence of cogwheel rigidity in patients on lithium maintenance.

A PARKINSON-LIKE syndrome that includes tremor, rigidity (including occasional cogwheel rigidity), and salivation was recognized as one of the side effects of such neuroleptic medications as phenothiazines and butyrophenones shortly after their introduction on the drug market (1). Simpson and associates developed (2) and extensively tested (3) a scale, based on the clinical evaluation of various symptoms, that can quantify the severity of this syndrome. Neuroleptic-induced extrapyramidal symptoms are thought to result from the catecholamine blocking action of these drugs, which induces an imbalance in the parts of the central nervous system that control motility; they are known to respond to anticholinergic agents.

The motor disturbance most frequently induced by lithium is evidenced by a fine, rapid tremor. Its frequency is about 10 cps in contrast to the 5–6 cps noted in Parkinson's disease; it is usually not accompanied by rigidity and it does not respond to anticholinergic drugs (4). These differences suggest that the mechanism of action of lithium is different from that of neuroleptic drugs.

However, a recent paper by Shopsin and Gershon (5) described the occurrence of cogwheel rigidity in more than half of a group of patients receiving lithium therapy for over a year. We therefore decided to examine the frequency of this symptom in our outpatient lithium maintenance clinic, employing the rating scale that we have used extensively for a large number of studies over many years.

Dr. Branchey is Research Psychiatrist and Dr. Simpson is Principal Research Psychiatrist, Rockland Research Institute, Orangeburg, N.Y. 10962. Dr. Charles is Director, Outpatient Psychiatric Department, Bergen Pines County Hospital, Paramus, N.J.

METHOD

Thirty-six outpatients (11 male and 25 female), with a mean age of 46.1 years, who had received lithium for a period ranging from 6 months to 7 years comprised the study population. There were 33 manic-depressive and 3 schizo-affective patients. None of the patients had received neuroleptics for at least 6 months; 8 of them were taking antidepressant medication in addition to lithium. In all patients, lithium serum levels were within the therapeutic range (0.6–1.2 mEq/liter).

Patients underwent a neurologic examination at the time of their regular outpatient visit. The Neurological Rating Scale for extrapyramidal side effects, developed by Simpson and Angus (3), was used to record the severity of symptoms. The scale consists of 10 items, with a severity rating range from 0 to 4. Seven of these items (gait, arm dropping, shoulder shaking, elbow rigidity, wrist rigidity, leg pendulousness, and head dropping) are related mostly to the level of rigidity; the other items are tremor, glabella tap (which measures the severity of induced blepharospasm), and salivation. An additional item, cogwheel rigidity (also rated from 0 to 4), was added to the original scale for the purpose of this study and measured the amount of rapidly fluctuating resistance to stretching of the patient's forearm by the examiner while the patient remained passive.

In addition 15 patients were reexamined by the investigator who participated in the development of the scale (G.M.S.), and several patients were examined more than twice. In view of the fluctuating nature of extrapyramidal symptoms (2), the highest score was recorded for those subjects examined two or more times.

RESULTS

Only 3 of the 36 patients had some amount of cogwheel rigidity (score of 1); this occurred together with other limb rigidity and tremor of the extremities. These 3 patients had been taking lithium for 2 years or more. Six other patients had rigidity (not of the cogwheel type) and tremor; 15 showed tremor but no rigidity, and 2 had rigidity but no tremor. Four patients who showed a positive response to glabella tap were among the ones showing evidence of tremor. The 10 remaining patients appeared to be free of neurologic symptoms. It should be pointed out that the degree of rigidi-

ty observed in the 11 patients with positive ratings was very low. None of the individual items related to rigidity was scored higher than 1, a rating that could occasionally be observed in a patient who does not relax completely. The low level of rigidity is also indicated by the fact that usually only 1 or 2 out of the 7 indicators of rigidity were positive.[1] A fairly large number of patients (24 out of 36) showed tremor, which was fine and rapid and mildly or moderately intense. Very few patients had subjective complaints, and some were surprised to note tremor during the examination. There did not appear to be any systematic relationship between the duration of lithium treatment and the occurrence of tremor or rigidity.

DISCUSSION

These findings do not support the previously reported high prevalence of cogwheel rigidity among patients undergoing lithium maintenance therapy. Even the 3 patients who had been taking this medication for 6 years or more were without cogwheel rigidity on two separate measurements.

It is worth noting that all the patients showing cogwheel rigidity also demonstrated evidence of rigidity and tremor. Whether cogwheel rigidity is simply a combination of tremor and rigidity or a separate entity is debatable (6). A possible explanation for the high level of cogwheel rigidity in the sample examined by Shopsin and Gershon (5) may be that many of their patients had been previously treated with neuroleptics and that a certain amount of rigidity was present as a residual effect. One of us (G.M.S.) had previously reported the occurrence of extrapyramidal symptoms in patients whose neuroleptic treatment had been discontinued for more than 90 days (2).

The glabellar reflex has long been considered as pathognomonic of a lesion of basal ganglia, as seen in Parkinson's disease (7). Pearce and associates (8), however, also reported its occurrence in diffuse cerebral disease. Klawans and Goodwin (9) showed that the administration of L-dopa to patients suffering from parkinsonism decreased the severity of the glabellar reflex. Our observation of this symptom in 4 patients on lithium maintenance therapy is therefore an argument in favor of an extrapyramidal effect of lithium; the possibility that it indicates a nonspecific effect on the central nervous system cannot, however, be ruled out.

We noted tremor, in a mild or moderate degree, in 66% of the patients. This frequency of occurrence is comparable with that reported by others; according to Vacaflor and associates (10), tremor can be found in up to 80% of patients taking lithium. The tremor observed in this study was fine and rapid, essentially different from that of the neuroleptic-induced extrapyramidal syndrome.

It is possible that the long-term use of a drug such as lithium may produce side effects that are not clearly observed following shorter periods of administration. For instance, it is now well known that the long-term use of neuroleptic drugs can induce a complex dyskinetic syndrome; it took many years of extensive use of these drugs before the dyskinetic syndrome was properly recognized and identified (11). Our findings in patients maintained on lithium for up to a few years are essentially negative; however, a rather high occurrence of tremor, an occasional glabellar reflex, and a low level of rigidity were noted. In view of the increasing use of lithium maintenance therapy and our few positive findings, a careful monitoring of the neurologic conditions of patients treated with lithium seems warranted.

Catatonia, Gastric Hyperacidity, and Fatal Aspiration: A Preventable Syndrome

BY ROBERT F. BORT, M.D.

Sudden death from aspiration pneumonitis during acute catatonia is a generally recognized but poorly understood occurrence. The author describes a case in which a schizophrenic patient died following aspiration of gastric contents. In view of findings that suggest that the acidity of gastric contents is related to morbidity following aspiration, he recommends that liquid antacid medication be given routinely to catatonic patients.

SUDDEN DEATH in patients with schizophrenia is not uncommon, especially among older and chronically ill patients (1, 2). The cause of death has been attributed to cardiac arrhythmia, hypotension, and aspiration of gastric contents (1–5). Fatal aspiration appears to be related to a primary dysfunction of esophageal motility in schizophrenic patients (5, 6) and unrelated to the side effects of phenothiazines on esophageal function (3, 4, 7). Some recommendations for the prevention of fatal acid aspiration can be derived from the following case.

CASE REPORT

A 19-year-old man was referred to a maximum security state forensic hospital for evaluation of competency to stand trial on a charge of armed robbery. He had a history of two prior hospitalizations for severe schizophrenic illness, which had responded each time to phenothiazine treatment.

On admission the patient was combative and incoherent, and his thinking processes were grossly disorganized. His initial behavior was reminiscent of the continuous pacing of a caged wild animal. The patient sat in his urine, smeared food about the seclusion room, and assumed bizarre postures. He became mute within several hours of admission.

Over the next 12 days the patient's catatonic excitement and hostility gradually decreased, and he began speaking again in two- or three-word phrases. Physical findings were within normal limits except for almost total immobility. The patient lay motionless and resisted attempts by the examiner to initiate any motion; e.g., efforts to flex an extremity were met with active extension efforts by the patient. During his 12th hospital day the patient suddenly developed respiratory distress (tachypnea and cyanosis) followed rapidly by hypotension and cardiac arrest. He was rushed to a nearby hospital emergency room, where he was pronounced dead on arrival.

A complete post mortem examination indicated that aspiration pneumonitis was the cause of death. Gastric contents were also found in the larynx. Toxicological findings were negative except for blood levels of chlorpromazine consistent with the prescribed dosage (600 mg orally every 24 hours).

Dr. Bort is an Instructor, Department of Psychiatry, University of Michigan School of Medicine, Ann Arbor, Mich., and a Staff Psychiatrist, University of Michigan Alcoholism and Drug Abuse Clinic, Riverview Building, 900 Wall St., Ann Arbor, Mich. 48105.

DISCUSSION

Standard psychiatric textbooks generally discuss the management of catatonic patients in terms of psychological and somatic treatments. Any mention of the high risk of aspiration in acutely ill, withdrawn catatonic patients is notably absent.

Cameron (1) reported a high mortality rate from aspiration pneumonitis in both acutely and chronically ill patients and described appropriate nursing care procedures related to proper positioning. To facilitate proper drainage of tracheobronchial secretions, high-risk patients should be positioned on their sides, with the foot of the bed elevated six to nine inches, a pillow placed between their legs and against their backs, and no pillow used under the head. Findings by Ribaudo (8), which indicated that the acidity of the gastric aspirate rather than the amount of the aspirate or amount of solids in the aspirate determined morbidity and mortality in aspiration pneumonitis should also be considered. Related studies in another high-risk group, parturient patients undergoing Caesarian section (9, 10), demonstrated the feasibility of using antacids to raise the gastric pH to a relatively safe level (pH greater than 2.4). This appears to markedly reduce the risk of morbidity when acid aspiration inadvertently occurs.

It appears that this latter approach should be adopted as part of the routine treatment of severely withdrawn catatonic or other immobilized schizophrenic patients. In addition to appropriate positioning to allow adequate oropharyngeal drainage, liquid ant-

acid medication, such as magaldrate suspension, should be given in dosages of 15 milliliters every 3 hours until the phase of the illness during which the patient is immobilized has passed.

Siblings as Therapists: A Behavioral Approach

BY NANCY BROWN MILLER, M.S.W., AND DENNIS P. CANTWELL, M.D.

Although many family therapy programs have taught behavior modification techniques to parents, few have involved siblings as therapeutic agents in the treatment of retarded, emotionally disturbed, or physically handicapped children. The authors describe their experiences with two families in which siblings were taught to use simple procedures to encourage desired behaviors in a disturbed brother or sister. They conclude that further investigation is needed to refine sibling training techniques and suggest that involvement in treatment programs may have beneficial influences on the normal siblings of disturbed children.

MOST SCHOOLS OF THOUGHT in child psychiatry emphasize that the nature of the interactions between a child and his family is an important factor that may contribute to the development of psychopathology in the child. However, they differ on which elements of the interactions are important and how family members may or may not be involved in treatment of the affected child (1). Practitioners who regard family members as agents in the genesis of psychiatric disorders in children usually exclude family members from treatment and work individually with the child. If the parents are worked with, they are worked with by separate therapists who focus on parental problems that may have contributed to the development of psychopathology in the child. Little or no time is spent giving parents practical suggestions on how to deal with their child's problem.

Family therapists, using a systems-oriented approach, treat all family members together, but most use a framework based on the same underlying principles as those therapists who work with parents and child separately. Recently, however, the behavioral school has taken the position that direct modification of a child's behavior in his natural environment by family members under the direction of a clinician might be more fruitful than the traditional office-oriented approach. Early efforts at using parents as therapeutic agents concentrated on discreet maladaptive behaviors of the child that were modified by operant techniques taught to the parents (2). Recently there has been a shift to the "parent-child interaction system" as the target for intervention. There is now concern not only for immediate behavioral change, but also for maintenance of new desirable behavior by all family members (3–5).

Direct family intervention at this level is aimed at providing parents with techniques and skills that will

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with the Neuro-Psychiatric Institute, University of California, Los Angeles, 760 Westwood Plaza, Los Angeles, Calif., 90024, where Ms. Miller is Social Work Training Coordinator, University Affiliated Facility, and Dr. Cantwell is Director of Professional Education, Division of Child Psychiatry and Developmental Disabilities.

enhance their parenting ability. Practitioners of direct family intervention hold that intervention aimed solely at changing the behavior of a child over a short period of time will have only limited success. However, intervention programs geared toward the improvement of parents' general competence will not only cause the child's negative behavior to decrease, but will result in an overall positive change in family interaction. The most successful exponent of this approach has been Gerald Patterson at the Oregon Research Institute in Eugene, Ore. He has parents attend a 10- to 12-week training program in parenting skills that requires parents to master one skill level before progressing to the next one (6).

Even sophisticated behavioral programs have all but neglected the use of siblings as agents of therapeutic change in the family. This paper will describe the treatment programs of two families in which siblings were involved as therapeutic agents. We will focus on the effectiveness of siblings in the treatment programs and problems encountered in using them as therapeutic agents.

CASE REPORTS

The impetus for systematically involving siblings in child treatment came from our experiences with two families in which siblings were successfully undoing the parents' efforts to carry out behavioral programs with target children. One 3-year-old boy was having about 12 temper tantrums a day. The parents had learned to ignore the tantrums by leaving the room, but the rate was not decreasing. The mother discovered that whenever she left, the child's 14-year-old sister entered the room and held him because she felt sorry for him and couldn't stand to hear him cry. Two sessions were held with the sister to explain social learning principles, and with great reluctance she was able to change her behavior. The tantrums decreased to two a day within 2 weeks.

In the second family, a 9-year-old autistic boy engaged in a high rate of what the family called "crazy talk." The parents had learned to ignore his inappropriate speech, but his four older sisters thought it was quite funny and "talked crazy" back to him. After the parents tried unsuccessfully to gain the siblings' cooperation, three sessions were held with them in the home to teach them how—and why—to ignore this behavior and to give him extra attention for talking appropriately. There was a significant decrease in the amount of "crazy talk," and the girls were also able to generalize their learning to other situations, such as whining and temper tantrums.

Case 1. Sally, age 4, is the youngest of five children, with three brothers and one sister. She was born prematurely with a congenital facial anomaly, and her early development was slow. When referred to us she was speaking in one- or two-word phrases that were unintelligible except to her family, would not play alone but insisted on being beside her mother most of the time, and engaged in frequent whining. Observations of family interaction showed that the whole family treated her with excessive indulgence. For example, when Sally moved around the room or played with toys, at least one member of the family would remind her to be careful. If she dropped a toy, someone would pick it up for her. The family reinforced her limited language skills by responding to her gestures and one-word interactions and by frequently anticipating her wishes. She was very shy and passive and showed little affect.

The treatment program consisted of working with the parents for four sessions to teach them principles of normal child development and social learning. Videotape sessions were held to give the parents feedback on their interaction with Sally. The siblings were then brought into the program; they observed the mother playing with Sally and she explained social learning principles to them in the therapist's presence. Videotape sessions were again held and the family members were able to observe their progress (7).

By the end of the 10-week program, Sally was speaking in four- and five-word sentences that were clearly intelligible. She would frequently say something and then ask, "Can you understand me?" The emphasis throughout the program was on facilitating Sally's development by shaping her speech and encouraging her to take risks and to play alone for longer periods of time. Eventually she was able to play alone for as long as 45 minutes. Follow-up observations 6 months after treatment indicated that all gains had been maintained and that Sally had become more outgoing and assertive in her family interactions.

Case 2. Andy, 11, was diagnosed as moderately retarded with autistic features. He had four older siblings: two sisters, 20 and 18, and two brothers, 16 and 15. Presenting problems included bizarre behavior, swearing, running away from home, stealing food from the refrigerator, and extreme hyperactivity.

The parents reported that the oldest daughter was willing to help take care of Andy but the other siblings were generally uncooperative. Efforts to involve them in Andy's care resulted in many family conflicts.

All of the siblings were willing to participate in the program. Treatment was begun while Andy was in a 5-day-a-week inpatient program and continued after he went home.

During the first two sessions, social learning principles were taught to the family through didactic materials and role playing. One behavior selected for intervention was taking food from the refrigerator, which occurred about 20 times a day. If a sibling saw this behavior occur, he or she would call the parents to intervene or would yell at Andy to stop. This would frequently be followed by chasing and giggling. A time-out procedure was established; anyone who saw a transgression would announce, "No stealing food, Andy. Three minutes of time out," and then take him to a predesignated chair in the corner of the hall, tell him to sit, and stand silently behind him. The first day, his 16-year-old brother caught him and carried out the intervention; about 1 hour later his 15-year-old brother repeated the procedure. About 3 hours later, Andy was observed as he went to the refrigerator, opened the door, closed it, and then went to the time-out chair and sat down. The problem did not recur.

One of the most effective interventions in this family was reprogramming the time each family member spent with Andy. All of the siblings had complained that their own time was frequently impinged upon when they were told to take

care of him. A schedule was made so that each sibling had 2 regular days "on call" during which he or she might have to help with Andy. On other days they were free to plan their own activities. In addition, each sibling was asked to spend 15 minutes a day in a one-to-one activity related to Andy's interests, such as playing with cars or going for a walk. During these sessions they were to encourage eye contact, coherent speech, and appropriate social behaviors. This aspect of the program was very effective in decreasing family arguing and in increasing positive interactions between Andy and his siblings.

BENEFITS OF SIBLING INVOLVEMENT

Several positive results of involving siblings in treatment programs have been identified.

1. Teaching new skills. Older siblings frequently "teach" younger siblings. The teaching is usually haphazard, sporadic, and based on the interests and attention span of the "teacher." By teaching siblings what to teach and how to teach, it may be possible to use this natural tendency to bring about actual gains for the target child. The tasks taught may be self-help skills such as dressing or eating, or more abstract skills such as recognizing colors, letters, or words.

2. Consistency: providing a united front. If all members of a child's environment react to selected behaviors in the same way, there may be more rapid learning of desired behaviors and a faster decrease of undesirable behaviors. This is true whether the planned intervention is praise, ignoring, or punishment. A consistent, predictable environment is particularly important for children with developmental disabilities. The advantages for children who require a longer time to learn of a family environment in which everyone works together to produce behavioral change are obvious.

3. Increased positive interactions. Negative interaction frequently results because siblings feel that their own lives are being impinged upon by the needs of the target child, who may also receive more parental attention and "get away" with more. By structuring both the amount and content of the time siblings spend with the target child, they can have successful, positive experiences together and know that the family is working together in a constructive, consistent manner.

PROBLEMS IN SIBLING TRAINING

1. Attention span. Sessions should be well planned and made up of a variety of short segments that alternate didactic teaching with active role playing and behavioral rehearsal. Length of sessions will vary with the age and behavior of the siblings, but generally 1 to 1½ hours is a maximum limit.

2. Sharing family secrets. We observed on several occasions that siblings did not feel comfortable talking about each other or their parents. This was particularly clear in one family in which the father had apparently spanked the target child rather severely, contrary to instruction. One of the siblings blurted this fact out, and the father gave him a harsh look and denied it. Such situations are difficult for both parents and children, and it is important to establish rules at the very beginning of the program, including a rule that all behavior in the family that is observed by anyone is subject to discussion in the meetings.

3. Following through on assignments. Siblings occasionally forget to write down a required assignment unless they recognize its importance. It may be necessary, especially in the early stages of treatment, for the therapist to call the family between sessions and talk to each family member about his progress in the program. The mother or father or a specified sibling may be "manager" of the program for a week to see that assignments are carried out.

4. Presence of target child. Trying to carry out an organized, efficient session can be very difficult when the referred child is present, particularly when the problem behaviors are hyperactivity and short attention span. In Andy's family, the therapist decided early that one target behavior should be independent play, but the program was only partially successful in achieving this goal.

It would be ideal to have the child present for only a part of each session to allow the family to practice new behaviors. However, finding a babysitter for many problem children is a difficult endeavor. A babysitter in the clinic may provide a workable solution to this problem.

5. Participation by family members. The dominating parent and the passive child, or other comparable combinations, present problems that require the therapists's active intervention during sessions. Siblings often "talk for" each other, and parents often "talk for" the children. The therapist needs to be in control of who talks when to assure equal participation by all family members.

DISCUSSION

More than 80% of the children growing up in the United States have siblings (8). Although much has been written about the importance of peer relationships to child development (9) and such terms as "sibling rivalry" and the "middle child syndrome" are used as if they represent some specific situation or syndrome, almost nothing of substance is known about the influence of siblings on each other (10). It is only natural to speculate that sibling relationships are important because of the amount of time and space they share and because of the natural hierarchy that exists simply because of birth order.

The interaction between siblings duplicates in microcosm most of the significant social interaction experiences that the child faces as he or she goes through adolescence and adulthood. Patterns of loyalty, and helpfulness and protection, or of conflict, domination,

and competition may be first learned by a child in relationships and interactions with siblings (9). These patterns may later be generalized to other social relationships. Because of the intense long-term relationships that siblings have with each other, we may assume that they influence and control, or attempt to control, each other on a daily basis. It seems logical, then, that siblings ought to be involved in behavioral modification programs that use family members to effect therapeutic changes in family interaction.

We have described the results of involving siblings in the treatment programs of two families. Both positive results and problems ensue when siblings are involved actively in treatment programs. The programs described here are only a beginning effort to understand the nature of sibling relationships and maximize positive social interaction among family members. Much further research is needed to develop and refine sibling training techniques.

More research is also needed on the effect of involving siblings in the training program on the siblings themselves. Although it is generally known that both intellectually retarded and physically handicapped children are at risk for the development of behavior disorders (11, 12), it is less well known that the normal siblings of these children are also at significant risk for the development of behavior disorders. The mechanisms of this situation are not well known, but some investigators have suggested that the development of behavior disorders in normal siblings of handicapped children is due to the distortion of family relationships that occurs as a result of a handicapped child in the family (12, 13). If this is the case, involving siblings in training programs might help prevent the development of behavior problems in the siblings themselves. As demonstrated in one family discussed above, a positive aspect of involving siblings in the training program is the development of increased positive interactions between the sibling and the target child. If negative interaction between the sibling and the target child is one of the causes of behavior disorders in the sibling, we might expect increased positive interaction to prevent or ameliorate behavior problems of siblings.

We hope that this paper will stimulate other professionals to investigate methods for effective involvement of siblings in behavior change programs.

LETTERS TO THE EDITOR

Death, Creativity, and Depression

SIR: In "The Madness of Art" (October 1975 issue), Professor Leon Edel beautifully described the phenomenon of chronic depression in creative individuals, which he feels is causally related to a preoccupation with death. While death has been the theme of many masterful aesthetic works and many artists do seem very concerned with this subject, I suggest that this interest can better be explained as a secondary elaboration, not the source of depression. If this were so, chronic frustration could be the basis for a prototypical psychodynamic formulation.

My hypothesis is based on one of the few "facts" about creativity upon which all students agree, Henri Poincaré's four stages of the creative process—preparation, incubation, illumination, and verification.

The creative artist always carries with him an awareness of those things he wishes to create. His first task is gathering background. The preparation then settles into appropriate (although sometimes unusual) perspective during the incubation period. This is necessary before illumination can take place. It is during the incubation phase, when he has achieved an appreciation of that which he wishes to create, that the artist faces great stress. He constantly refines his approach to the creative end; he reworks his preparation and receives partial rewards. He has a compelling need to repeat this process until it yields results. Realizing the potential of his desires, he values the striving process, but the overall effect is that he feels inadequate in his attempt to achieve illumination. The artist then accepts a resulting chronic depression.

When a single illumination does take place, it rewards the artist's choice of lifestyle. Even then, however, there are several other parallel means by which the artist perpetuates his depression. One of these is his heightened awareness of death. By virtue of a sensitive appreciation of the possible, the artist sees creative potential in coming to terms with death. This challenge becomes another frustration that can heighten depression. Thus death can be viewed as more "grist for the mill." It is the character and cognitive style that cause the frustration and depression.

Rauwolfia Derivatives and Breast Cancer

SIR: Studies published in 1974 by investigators from the United States (1), Great Britain (2), and Finland (3) showed that the incidence of breast cancer in hypertensive women over 50 treated with rauwolfia derivatives is significantly higher than that found in parallel control series. These data suggested a causal link between rauwolfia and breast cancer. The results of a U.S. study published in 1975 (4) did not support this hypothesis.

The first three studies identified the problem and indicated the need for further research and for caution in the use of rauwolfia in women at risk for breast cancer. There are some important points to be clarified, such as dosage, time of exposure, and causal mechanisms (5). If the possibility of carcinogenic action is related to the prolactin release caused by rauwolfia, an important problem could arise for psychiatrists (6) since prolactin is known to increase in some people receiving phenothiazines.

The research division of the Hôpital St. Michel Archange in Quebec and the psychiatric department of Laval University in Quebec are preparing a special investigation to explore the hypothesized link between the use of reserpine and other neuroleptics and the incidence of breast cancer in women.

Some preliminary data from this study may be of interest. We have found that the percentage of women operated on for breast cancer during a 28-year period before the introduction of rauwolfia derivatives and other neuroleptics (1925–1953) was not significantly different from that found after the introduction of these drugs (1954–1974).

From 1954 to 1974, 53 women were operated on in the same hospital for breast cancer. Their mean age was 59 years (range, 31–90). For each case of breast cancer, a female patient from the same hospital matched for year of operation and for age (within 5 years) was selected as a control. The mean age in the control group was 59.4 years (range, 32–85). The control patients had been operated on for minor surgical complaints. The preoperative exposure of these two groups to reserpine was examined, and it was found that the breast cancer group had not been exposed to reserpine more often than the control group.

We also compared the incidence of breast cancer in two groups of 70 women each, one treated with reserpine and other neuroleptics and the other with different neuroleptics excluding reserpine. The mean age in the former group was 59.5 years (range, 30–82) and in the latter 60 years (range, 32–83). The length of reserpine treatment ranged from less than 6 months (N=30) to 9 years (N=3). Four women in each group were operated on for breast cancer. Thus the incidence of breast cancer in the two samples was the same. We should emphasize that some of the reserpine patients were treated with high doses (i.e., reserpine was used as an antipsychotic) and some were given reserpine as an additional drug prescribed for hypertension.

"Primary" Prevention?

Sir: After a careful review of the excellent article "We Help Each Other: Primary Prevention for the Widowed" by William F. McCourt, M.D., and associates (January 1976 issue), I question the use of the term "primary." Wouldn't "secondary" and in some cases "tertiary" have been more appropriate, especially when it is stated that "We perceived the recently bereaved as being in a state of acute crisis"?

Incidentally, on page A7 of the same issue, I noted that there is no committee on preventive psychiatry and I wonder why this is so.

On Jungian Psychology

Sir: I have noted a growing receptivity in psychiatry and among psychiatric residents in the last decade to Jung's theories. In order to determine whether this opinion is widely held in America, I submitted a detailed questionnaire to 357 directors of psychiatric residency programs and to 116 American members of the International Association of Analytical Psychologists; 48% of the former and 44.8% of the latter returned completed questionnaires.

Program directors stated that Jungian concepts were included in supervision of case material in 21% of the residencies. They also thought that psychiatric residents were receptive to Jungian analysis when first introduced to it; a mean of 6.5 was found on a scale from 1 (strongly reject) to 7 (strongly receptive). Program directors indicated that 23% of residents showed increased receptivity. The program directors saw increasing receptivity in 17% of psychiatrists and 20% of psychologists.

Jungian analysts were extremely optimistic about receptivity to Jungian psychology, believing there was a 96% increase in the past decade among university students, 63% among psychiatric residents, 57% among psychiatrists, and 72% among psychologists. Ninety-five percent of Jungian analysts favored greater participation in psychiatric training programs. While they perceived no change over the last decade in the receptivity of academic psychiatry to Jungian theory, they thought receptivity would increase during the next decade.

Jungian analysts ranked the concept of the collective unconscious and Jung's dream work as his most important contributions. They listed *Two Essays on Analytical Psychology* (1), *Memories, Dreams, Reflections* (2), and *Man and His Symbols* (3) as the three most important books to recommend to psychiatric residents.

There currently seems to be a zeitgeist for subjective inner world experiences as well as greater tolerance for a wide variety of therapies and a decreasing domination of psychoanalysis. There is also a greater awareness of the non-Western world, oriental religions, and the esoteric. It is my opinion (which the facts neither support nor refute) that there is a growing understanding of the practical value of Jungian psychology in psychotherapy, of dream analysis, and of having an alternative view of depth psychology. The evidence, to the extent that the opinions I have summarized are valid, suggests that there has been and will continue to be a growing influence of Jungian psychology in American psychiatry, psychotherapy, and analysis.

Another Leaderless Group

Sir: As a member for over two years of a leaderless group that began while its members were psychiatric residents in various stages of training, I read with much interest "History and Analysis of a Leaderless Group of Professional Therapists" by Winslow Hunt, M.D., and Amnon Issacharoff, M.D. (November 1975 issue). The group I belonged to consisted of six men in two San Francisco training programs, who ranged in age from their late twenties to early thirties.

The core of the final group were residents in a small community mental health program that assigned trainees to catchment areas in different parts of the city; they consequently had little contact with one another. The residents met irregularly to discuss their assignments and alternatively to gripe or praise their relatively unstructured and unsupervised program. By the end of the first six months a group had formed, a regular meeting time had been designated, and a meeting place was selected. At the end of the first year, two members transferred to another program and a member from that program replaced one of the original members. New trainees were invited to participate, but by the second year the group had in effect closed.

The group was used for feedback about patients, supervisors, and coworkers as well as ourselves. All six of us were in analytically oriented psychotherapy. The tacit group commandment, "Thou shalt not leave treatment," was an important cohesive force. Our frustration, anger, resistance, ad-

vances, and retreats were elaborated in the group. Intragroup rivalry focused on the prominence of our analysts in the community. Not-so-subtle jokes were made about whether the "sicker" group members needed daily analysis or were receiving "supportive" biweekly psychotherapy and whether the "healthier" could undergo daily analysis or were independent enough to need only biweekly treatment.

Five of the six members were single, and the group served an important weekly socializing and friendship function. In the second year, as members became closer, dinners and brunches alternated with weekly meetings. However, the group was possessive of its members and we were both pleased and upset when members entered serious relationships.

As members finished residency training and became job seekers or military "obligated volunteers," the group suffered many shocks. Intragroup rivalry was apparent in regard to academic appointments, private practice partners, and acquisition of patients. Three of the original six members declared conscientious objector status and the ethics of entering or not entering military service were hotly debated. The group continues in its fourth year.

Regression and Borderline Patients

SIR: In "Psychotherapy of Borderline Patients: The Influence of Theory on Technique" (October 1975 issue), Henry J. Friedman, M.D., raised the issue of the usefulness of regression in the treatment of borderline patients. In a community mental health setting where we attempt to minimize state hospital referrals, we see a significant number of individuals referred for such treatment where the principal problem appears to be massive regression. Many of these patients have the characteristics of the borderline syndrome.

Dr. Friedman is to be congratulated for drawing attention to this issue. I would be most interested in a more extensive discussion of regression, encompassing the clinical situations where regression is likely and the therapeutic techniques that can effectively counteract or limit regression. Perhaps Dr. Friedman could provide further information or references on this topic.

JAMES SPENSLEY, M.D.
Sacramento, Calif.

Dr. Friedman Replies

SIR: One common theme that emerges from examination of regressive states in borderline patients, whether they occur during psychotherapy or in patients' personal lives, is an intense relationship with an individual or therapist who has failed to set realistic limits on the nature of the interaction, either therapeutic or personal.

In my review of histories of patients who have shown massive regression, there have been some recurrent themes. While an exhaustive summary is impossible due to space limitations, these include 1) an inexperienced therapist, 2) excessive reliance and emphasis on transference, not as a naturally occurring phenomenon but as something to be provoked and sought out, 3) a tendency to confuse the patient's illness and regressive tendencies with a total inability to cope, and 4) a therapist who struggles to work with a patient who has inadequate motivation to change.

Clinically, borderline patients tend to get lost in the transference so that they in essence forget the actual purpose of their treatment. One of the main therapeutic tasks related to this tendency is a need for the therapist to be active in keeping the realistic aspects of the doctor-patient relationship in clear view for the patient and for himself.

The goal of limit setting in the psychotherapy of borderline patients is not to prevent all regression. This, of course, would not be possible even if it were desirable. The aim is rather to keep the regression at a workable level that is compatible with constant efforts to develop insight. This is not as simple with borderline patients as it is with more healthily neurotic individuals who have greater degrees of ego strength.

Unfortunately, the false dichotomy between expressive psychotherapy and supportive psychotherapy has persisted. Neither is effective for borderline patients—"letting it all come out" in expressive psychotherapy tends to lead to disorganization in borderline patients, and strictly supportive treatment fails to lead to adequate insight and emotional growth. The answer to this difficult clinical problem posed by borderline disorders seems to me to lie in increased flexibility in the application of psychoanalytic understanding of the variability of ego states between neurotic and borderline patients. If he recognizes this difference, the experienced clinician will make specific adjustments in his therapeutic technique that will decrease the regressive pressure on the patient when it is essential to do so. An inventory of such crucial points would require an additional paper. However, the general principle of applying less stress to the patient in tense, difficult clinical situations will suffice to allow most treatments to continue without disruptive regression. This maneuver will strengthen the therapeutic alliance and allow for further insight-oriented work at a point of less stress in the patient's life or transference.

References on the limit-setting aspects of working with borderline patients are scarce (1, 2). The content of the regression has attracted far more interest in the literature. It is my impression, however, that in actual clinical work the principles of limit setting have been widely accepted because they do work and permit the outpatient treatment of patients who otherwise would require lengthy and debilitating hospitalizations.

Psychodynamics in Medical Education

SIR: I was much puzzled by "The Selection of a Psychiatric Curriculum for Medical Students: Results of a Survey" by Warner Johnson, M.D., and John Snibbe, Ph.D. (May 1975 issue). Among the 10 topics consistently ranked as most

important were suicide evaluation, the dying patient, psychophysiologic disorders, the doctor-patient relationship, drug and alcohol abuse, sexual problems, and differential diagnosis. I think it would be impossible to learn about these topics and develop clinical judgment and evaluative acumen without an understanding of the basic psychodynamic issues.

I realize that medical students, medical residents, and even psychiatric residents are shocked by the emergence of unconscious fantasies, and that they seek quick diagnosis and fast results. Nevertheless, psychoanalytic psychology should be taught in a fashion integrated with clinical teaching in small groups, so that both patients' and residents' resistances can be analyzed and understood. Medical training should not encourage a flight from unconscious material. Psychiatric educators must make a serious effort to teach psychodynamic principles that are meaningful and relevant to those patients actually being seen by the residents.

I am not at all sure that psychologists, general psychiatrists, or other physicians even know what psychodynamics is (the science of motivation and control), or that there is a dynamic, genetic, and adaptive balance of forces left over in the psyche from a primitive infantile mental life. This psychic trauma imposes countless distortions onto the current life of the individual, inhibits his ability to cope, and is obfuscated by many social crises, family illnesses, and much individual suffering.

HELEN STEIN, M.D.
Fresno, Calif.

Dr. Johnson Replies

SIR: We share Dr. Stein's concern about the findings of our survey. We feel it is important to respond to her letter because it probably represents the feelings of many dedicated teachers who find that course material important to them may be less valued or needed by others.

Unfortunately, psychiatric education in medical school has not been very well regarded by our medical colleagues. If Castelnuovo-Tedesco's findings (1) are representative of physicians' opinions about the quality and relevance of psychiatric training in medical school, then we educators must return to the proverbial drawing board. Indeed, it would be well for us to reevaluate totally our past teaching efforts and make greater use of modern educational principles—even if it means making dramatic changes in our instructional practices.

We believe that an important first step toward placing psychiatric teaching on a more objective footing is to define clearly the curriculum to be taught. Our study was meant to do just that. It was, in essence, a needs assessment survey determined by a consensus of many physicians and mental health professionals. This technique reduces the effect of individual biases, which can easily distort curriculum selection. Like Dr. Stein, we were somewhat surprised at the survey findings and their implications for psychiatric education. Nevertheless, the results of the study were quite clear about what should and should not be included in a psychiatric curriculum for today's medical students.

One can, of course, dismiss the study and insist that future presentations in psychiatry be modeled after those of the past or in accordance with personal preferences. In our opinion, to do so would be a disservice to our students and future colleagues. We cannot justify the assumption that any single system of theory or course work that is important for us is necessarily relevant for nonpsychiatric physicians. As educators, it is our task to prepare our students to meet *their* future practice needs. With our track record, we need all the help available in devising a useful curriculum. It is very likely that practicing physicians can educate us about what psychiatric knowledge and skills are needed most in their day-to-day practice of medicine.

Apparently, many of our teaching efforts have not proven useful, and formal courses in psychoanalytic theory and psychodynamics rank among them. It is important for us to review why these courses and others have not been well received. Dr. Stein suggests that the phenomenon is due to resistance or a "flight from the unconscious." Perhaps this is so, but we feel that antiquated teaching methods, inadequate preparation of students to deal with complicated theory, and lack of practical clinical relevance are other possible explanations.

We are currently investigating the problem from the medical student's perspective and hope to have more data available soon. Curriculum selection is a task of great importance. At the present time we feel that it can be best accomplished by consensus.

A Medical Student's Experience with Akathisia

SIR: Because the unpleasant but treatable extrapyramidal side effects of antipsychotic drugs are not often experienced by medical personnel, and because one of these side effects, akathisia, is not infrequently misdiagnosed, I would like to describe an akathisia reaction I experienced after receiving 1 mg of haloperidol intramuscularly during a neuroendocrine research study.

At 8:00 p.m. I had an intravenous heparin block inserted in an arm vein, from which blood was withdrawn at intervals. At 9:00 p.m. I received 1 mg of haloperidol intramuscularly. I felt drowsy by 9:20. By 9:30 the drowsiness had dissipated and was replaced by a diffuse, slowly increasing anxiety. My uneasiness soon began to focus on the idea that I could not possibly sit still for the rest of the experiment. I imagined walking outside; the idea of walking was particularly attractive. I could not concentrate on what I had been reading. Contrary to my expectations, the anxiety was not relieved by the removal of the IV at 10:00 p.m. As soon as I could move, I found myself pacing up and down the lab, shaking and wringing my hands. Whenever I stopped moving, the anxiety increased. Performing the simple tasks of centrifuging and pipeting the blood samples was difficult, and it took maximum concentration to sit still long enough to complete the task. I imagined bicycling home rapidly—the thought of rapid motion was again appealing.

The reaction peaked at 10:30 p.m., about the time I finished with the samples. I walked very quickly to my bicycle, which brought some relief from the anxiety. At home, I walked rapidly several times around the apartment complex

and then ran up and down the long driveway. Once inside my apartment, I did a little jig, moving my arms and legs quickly. By midnight the intensity of the reaction was decreasing. To have something to do, I gladly washed a large pile of dishes that were not mine—normally not my favorite activity. I was able to get to sleep by 2:00 a.m., two hours past my usual bedtime.

Two features of this akathisia reaction impressed me. First, the intensity of the dysphoria was striking. With the possible exception of going on stage on an opening night, I cannot remember any feeling of anxiety so intense. Second, the sense of a foreign influence forcing me to move was dramatic. Long before I thought of akathisia, or even discovered that moving made me less anxious, I was pacing and wringing my hands. Had I been asked why I was behaving this way, I can imagine I would have looked at my hands and feet in amazement and responded, "I don't know."

I hope that my opportunity to experience and describe this most unpleasant extrapyramidal side effect will alert others to the necessity of its rapid detection and treatment. I believe that warning patients of the possibility of this reaction is particularly important. The sense of a foreign force driving one to move, with the concomitant anxiety, might be extremely disconcerting to an uninformed patient who is already struggling with psychosis.

Palo Alto, Calif.

Depressive Disorder in Childhood

SIR: "Clinical Criteria for Psychiatric Diagnosis and *DSM-III*" by Robert Spitzer, M.D., and associates (November 1975 issue) reports an important step toward bringing psychiatric diagnosis into the mainstream of medical diagnosis. I would like to suggest that clinical diagnostic criteria also be applied to psychiatric diagnosis of prepubescent children. Modification of the *Research Diagnostic Criteria* (1) is necessary in order to apply the criteria to children. Several recent studies (2–4) have proposed criteria for diagnosing the affective disorders in prepubescent children. An example of the diagnostic category of "childhood depression" that could be used in *DSM-III* is shown below:

Depressive Disorder in Childhood

A. Both dysphoric mood and self-deprecatory ideation. The dysphoric mood includes hypersensitivity, crying spells, negativity, "difficult to please," and statements or appearance of sadness, loneliness, unhappiness, hopelessness, and/or pessimism. The self-deprecatory ideation includes beliefs of persecution, desire or attempts to run away or leave home, death wishes, suicidal thoughts or attempts, and feelings of being worthless, useless, "dumb," stupid, and/or ugly. Dysphoria and self-deprecation must be prominent and relatively persistent but not necessarily the most dominant symptom.

B. At least two of the following eight symptoms are required to have appeared as part of the episode.

1. Aggressive behavior (agitation).
2. Sleep disturbance.
3. Change in school performance, including frequent complaints from teachers of daydreaming, poor concentration, or poor memory, loss of usual work effort in school subjects, and loss of interest in nonacademic school activities.
4. Diminished socialization, to include decreased group participation or social withdrawal.
5. Change in attitude toward school, including school phobia.
6. Somatic complaints, including nonmigraine headaches, abdominal pain, or other somatic concerns.
7. Loss of usual energy (includes nonschool activities).
8. Unusual change in appetite or weight.

C. Dysphoria and self-deprecation must be a *discrete change* in the individual's usual behavior and must be present for longer than one month. Momentary shifts from normal to a state of dysphoria and self-deprecation (usually associated with acute turmoil) are excluded.

D. During the episode the individual must have impaired functioning socially, with family, at home, or in school because of symptomatology.

The use of diagnostic clinical criteria in *DSM-III* will help to standardize research in the diagnosis and treatment of childhood psychiatric disorders.

ROGER A. BRUMBACK, M.D.
Bethesda, Md.

Dr. Spitzer Replies

SIR: We are delighted that Dr. Brumback considers the incorporation of specific clinical diagnostic criteria in *DSM-III* an important step in the development of our field. What amazes us is that we have yet to hear anyone raise the issue of the potential dangers of this approach! Perhaps we are uncomfortable about suggesting something that is apparently so devoid of controversy. As to Dr. Brumback's specific proposal, inclusion in *DSM-III* of "depressive disorder in childhood," the subcommittee of the Task Force on Nomenclature and Statistics that deals with disorders specific to childhood has given this matter considerable thought and is familiar with the references cited.

There is controversy regarding the presence of clinical depression in children and, if it exists, whether or not it is fundamentally different from depression in adults. We feel that whenever clinical depression is judged to be present in a child, use of either the adult major or minor depressive disorder categories should be sufficient. We are not convinced that depression in a young person is a fundamentally different disorder than it is in adults. (Actually, the criteria Dr. Brumback proposes are very similar to the criteria for minor depressive disorder in the *Research Diagnostic Criteria*.) This would be similar to the practice of using the adult diag-

nosis of phobic or obsessive-compulsive disorder when either condition appears in a child.

It may be that there is a specific form of depression that occurs only in children and that we are mistaken in not including such a category in *DSM-III*. Only research studies that employ operational criteria for defining diagnostic categories can answer this question.

ROBERT L. SPITZER, M.D.
New York, N.Y.

Was "Sociopathy" Ever a Diagnosis?

SIR: " 'Sociopathy' and Its Synonyms: Inappropriate Diagnoses in Child Psychiatry," by Dorothy Otnow Lewis, M.D., and David Balla, Ph.D. (July 1975 issue) contains the strangest logic I have ever seen in the *Journal*. The authors recommend abandonment of the diagnosis of sociopathy because it "has lost its value." It is strange indeed to see such a suggestion in the *Journal*, since as far as our Association is concerned, sociopathy is not and never has been a diagnosis. It has never been a synonym for antisocial personality, which *is* a diagnosis. I was particularly perplexed to read that "Established in the adult nomenclature, [which it never was] the diagnosis of sociopathy infiltrated the new section of Behavior Disorders of Childhood and Adolescence." Because I wrote that section and have never accepted the diagnosis of sociopathy nor permitted it to be used on my service, this statement leaves me at a loss.

The authors cited two cases of adolescents dismissed by hospitals as "sociopathic." As a result of this dismissal, the correct diagnosis was missed and treatment was not instituted. On the basis of these examples, Drs. Lewis and Balla wish to delete a section of our diagnostic manual.

I must heartily agree that diagnosis in this area is often regrettably sloppy. However, any experienced clinician has seen instances in which the diagnosis of mental retardation has been incorrectly made in a child with a sensory or language deficit. Would the authors suggest that we should delete the diagnosis of mental retardation from our diagnostic manual for this reason? The diagnosis of retardation may also result in failure to treat and may have adverse consequences for the life of the child so diagnosed. The fact is that we *need* the diagnosis of mental retardation. During my lifetime, the accepted term for this diagnosis has changed from feeblemindedness to mental deficiency to mental retardation, but the concept was and is a necessary one.

In the same way, we need to recognize a deficit in the capacity of some persons to relate with empathy to others. This deficit commonly results in a failure of socialization. This is the essence of the antisocial reaction in *DSM-I* (1) and the antisocial personality in *DSM-II* (2). It is *one* of the elements that contribute to instances of antisocial behavior and crime. Since this is a fundamental defect in character structure and has far-reaching and, at times, catastrophic consequences, we cannot ignore it.

An important cause of this failure of socialization—the lack of an opportunity to develop empathy with a parent person in early life—was recognized by Loretta Bender (3), who was cited by Drs. Lewis and Balla, although they do not seem to understand what she wrote. It results in a guiltless, shameless, and often hostile aggressive personality. Attempts to shape a suitable diagnostic category for this type of defect, the authors point out, have a long history.

The concept of "moral insanity," which they mention, was subject to attack on religious grounds. In the words of John Ordronaux, Professor of Medical Jurisprudence at Columbia University, "The only disease to which the moral nature is subject is sin." This concept was replaced by "psychopathic personality" and in *DSM-I* by antisocial reaction, which stressed the lack of empathy of these individuals, describing them as "maintaining no real loyalties to any person, group, or code."

"Sociopathy" does not appear in either *DSM-I* or *DSM-II*. "Sociopathic personality disturbance" appears in *DSM-I* as a heading that includes antisocial reaction, dyssocial reaction, sexual deviation, and addiction (both alcoholism and drug addiction). In *DSM-I* all homosexuality (which our Association has recently decided is not a mental illness) was classified as a sociopathic personality disturbance. If we accept Drs. Lewis and Balla's term, then before our Association voted, all homosexuals were sociopathic.

"Behavior disorders of childhood" in *DSM-II* arose not from any theoretical preconceptions, but empirically from the repeated experimental finding that the same six symptom clusters exist in populations in various clinics in both this country and Japan. Lewis and Balla will find reference to these studies in my book *Behavior Disorders of Childhood and Adolescence* (4). These are three behavior disorders that come within the range of what they call "sociopathy."

The "group delinquent reaction" listed in *DSM-II* is a pattern of peer group rebellion often associated with strong group loyalty. In such instances it is a *socialized* response within a rebellious group. Particularly vulnerable is the adolescent boy who developed the capacity for empathy with others under his mother's nurture in his early years, who comes from a large and impoverished family living in a disorganized delinquency area, and who lacks an adequate father figure.

Two patterns of unsocialized delinquency are listed. They represent the classical alternatives of fight and flight. The "unsocialized aggressive reaction" is a pattern of attack in a world seen as hostile and develops most typically in the child who has good muscles, who has been and feels rejected, who has been treated inconsistently but has also had some degree of overprotection or shielding from the authorities in his aggressive behavior, and who consequently has the courage to attack. The "runaway reaction" involves repetitive running away from home overnight or longer and is prone to develop with the more severely rejected child who feels utterly beaten down, has a very bad self-image, and seeks to run from his problems.

Contrary to the negative treatment attitudes that Drs. Lewis and Balla said their two cases met, these three behavior disorders are treatable and probably offer a more favorable prognosis in general than the two cases they cite as missed diagnoses. To be sure, they are not effectively treated with drugs or traditional psychotherapy, but in the structured environment of a good training school, group delinquents may be rewarding to work with. The unsocialized delinquents who lack the capacity for empathy with others must be worked with patiently in a structured situation in terms of their egocentric self-interest. At younger ages, unsocialized children typically respond to the structure, consistency, and behavior modification methods of a children's psychiatric ward. Adolescents may require the structure of a training school or a security hospital. The Robert F. Kennedy Youth Center in Morgantown, W. Va., successor to the old National Training School for Boys in Washington, D.C., has reported a good degree of success using a structured token

economy with unsocialized aggressive boys. I have also seen many good results of treatment at the Iowa Training School for Boys.

Let us not throw out the baby with the bathwater. It does no good to delete needed and appropriate diagnostic categories because they are misused.

Dr. Lewis Replies

SIR: I prefer at the present time not to reply to Dr. Jenkins's letter, since I am working on a book that will provide a more comprehensive statement.

I have, by the way, made it a point to discuss his letter and other issues about delinquency personally with Dr. Jenkins. He therefore knows that I have not ignored or avoided his views.

DOROTHY OTNOW LEWIS, M.D.
New Haven, Conn.

Focusing on Television

SIR: I would like to suggest that the constant shifting of visual frames in television shows is related to the hyperkinetic syndrome. Television has emerged as the single major cognitive experience during the developmental years of huge numbers of children. Apart from the vapid and violent content of the programs, there are incessant changes of camera and focus, so that the viewer's reference point shifts every few seconds. This technique literally programs a short attention span and probably accounts for the almost hypnotic attraction television has for many of us.

A child conditioned to experience the world through television is then placed in a classroom where he is expected to learn from a static visual frame of reference. I suggest that the hyperactive child is attempting to recapture the dynamic quality of the television screen by rapidly changing his perceptual orientation. I also wonder if it is not possible that amphetamines control this behavior by providing a subjective experience comparable to the fleeting worlds of television and hyperkinesis.

Research with large samples and matched controls could test the hypothesis that with whatever other preconditions there may be, the hyperkinetic syndrome results from excessive television viewing during the child's early development. If this were confirmed, we would have additional reason to limit or proscribe television. However, this would probably be no more effective than other public health exhortations. Another approach might be to prevail upon television producers to modify techniques so that their programming is less noxious in style, if not content.

MATTHEW P. DUMONT, M.D.
Belmont, Mass.

A Television Stereotype

SIR: As a respite from the constant perusal of the psychiatric literature, I like to watch television occasionally. Within a three-week period, I, like millions of Americans, was treated to the following morsels. On November 12, 1975, "Starsky and Hutch" tracked down a psychopathic murderer dressed in aluminum foil ("to keep out the cosmic rays"). On November 13, "Harry O" attempted to infiltrate a psychotherapy group to uncover the murderer of two people. On November 16, "Bronk" sought a deranged, senseless bomber. On November 30, "Bronk" trailed two unstable, impulsive, screaming female revolutionaries who had kidnapped a wealthy man's son; one of the women was a drug addict.

My purpose is not to assail violence in television programming. Rather, I wish to point out that all of these stories link crime and mental illness so closely that I am afraid television viewers in general will begin to make an absolute association between mental illness and criminal behavior.

My sample of programs may have been biased by chance network programming schedules, and the shows I have described may be the only ones that link crime and psychiatric illness this season.

I would not deny that some mentally ill people do commit bizarre and sensational crimes, but TV programs appear to be including such people in their scripts far out of proportion to their actual numbers. If so, then we in psychiatry should attempt to give a counterbalancing, or at least a mitigating, education to the public on this topic. Otherwise, serious misconceptions may develop that could prove (if they have not already done so) detrimental to the welfare and rehabilitation of our patients. Obviously, this would also undo the considerable effort expended over many years toward removing the stigma of mental illness. Perhaps this letter will alert other psychiatrists to the potentially serious consequences of this type of television programming.

DANIEL A. DANSAK, M.D.
Washington, D.C.

Correction

The correct title of Paul Briquet's book referred to in "The Semantics of Hysteria Continued" (Letter to the Editor, January 1976 issue) is *Traité Clinique et Thérapeutique de l'Hystérie*. The staff regrets this error.

BOOK REVIEWS

Mental Health and Law: A System in Transition. U.S. Department of Health, Education, and Welfare Publication 75-176, *by Alan A. Stone, M.D. Rockville, Md., National Institute of Mental Health (Washington, D.C., U.S. Government Printing Office, distributor), 1975, 266 pp., $2.65 (paper).*

Many private practice psychiatrists are only half aware of the attack on established methods of psychiatric functioning by new law cases and legislation designed to make commitment more difficult to obtain, to press for deinstitutionalization, to protect more fully the civil rights of mental patients, and to establish new patients' rights. Institutional psychiatrists are more sensitized to the fact that they are being challenged to justify their decisions and to prove that they provide enough of the right kind of treatment to patients who are capable of benefiting from treatment. They are being required to demonstrate that their predictions of treatability and dangerousness are accurate enough to merit the authority they wield.

Dr. Stone, Professor of Law and Psychiatry at Harvard University, is acutely aware of the tensions and turmoil that exist in the mental health system because of the changing relationship between law and psychiatry. The National Institute of Mental Health's Center for Studies of Crime and Delinquency commissioned Stone to write a monograph on the present state of the interaction of the legal and mental health systems to focus more attention on transition phenomena. The result is what the author and the sponsor call a monograph, but it does not have the narrow limits that are sometimes associated with that term; it is a book, a remarkably far-ranging and comprehensive book, on the current status of legal psychiatry.

Stone has been thoroughly immersed in the transition he describes. As a result of a longtime debate with Prof. Alan Dershowitz, his civil-liberty-minded colleague at Harvard Law School, he has had to think through the problems of criteria for commitment and the usefulness of commitment. (Stone and Dershowitz have not yet come to a meeting of the minds.) As chairman of APA's Commission on Judicial Action, Stone has been the chief voice in deciding in which legal controversies APA should intervene and on whose side. (Although I serve on the commission, I have tried not to let this bias my appraisal of the book.)

Stone describes a mental health system that operates not in isolation, as many psychiatrists are accustomed to think, but in relationship to the criminal justice system and the welfare system. He states,

> What has happened in the last two decades is that in the name of reform, the professionals within each of these social institutions have taken on the roles, functions, and goals of each other.

In the field of psychiatry, he says, it could be argued that inflated claims concerning technical services that are provided have led to a huge array of mental health technicians, few of whom in fact have significant technical skills. Rather, much of what they do is the providing of personal care, attempting to engraft a meaningful human relationship on what poses as a technical service.

Another important discussion in this book deals with standards in mental health care. Stone feels that the 1973 federal legislation authorizing Professional Standards Review Organizations (PSROs) will force psychiatry to come up with tangible standards that will guide the courts in dealing with the appropriateness of commitment and treatment. Thus, he feels, one of legal psychiatry's greatest problems will be solved.

Among the important topics the author deals with are dangerousness, civil commitment, the right to treatment, the right to refuse treatment, institutional labor, mental retardation, the juvenile system, the aging, and sexual psychopaths and defective delinquents ("quasi-criminals"). There is also an excellent and up-to-date discussion of criminal responsibility and competency to stand trial. The final chapter deals with the role of lawyers in the mental health system. Because of a time lag between the writing of the manuscript in 1974 and its publication in 1975, Stone has added an appendix to bring the reader up-to-date with the current activity in legal psychiatry. He states that in this 12-month period, "There have been new legislative enactments, hundreds of reported cases, thousands of publications, and innumerable changes in administration and policy."

The book maintains a middle ground, recognizing that a great deal of psychiatric authority is exerted in ways that are not useful and infringe on the individual as well as the reality of psychic suffering and the need for help that sometimes require a paternalistic approach.

On almost every page of this book there are such thought-provoking statements as the following:

> When there are no alternatives, the concept of voluntariness is a charade.
>
> Dangerousness, like beauty, is to some extent in the eye of the beholder.
>
> One factor [often overlooked but worth mentioning] is the medically debilitating effect of not providing due process safeguards.
>
> It is ironic that States who exercise the power of removing children from their parents because of neglect will expose children whom they accept responsibility for to even greater depths of neglect.

Stone undoubtedly knows that there is no way to force his fellow psychiatrists to pay attention to the relationship between law and psychiatry until an outside agency—the government, the patient advocacy bar, personal injury lawyers, or reforming legislators—makes the situation impossible to ignore. However, if he cannot force psychiatrists to face up to all of the obligations and responsibilities that go with the practice of psychiatry, he has made it easier for them to be-

come better informed and to think more. He has described problems, advanced a number of useful solutions, given his own opinions, and brought an appreciable measure of clarity to a scene that has been obscure.

It is important that this book be widely circulated and widely read.

JONAS ROBITSCHER, J.D., M.D.
Atlanta, Ga.

Too Much Anger, Too Many Tears: A Personal Triumph Over Psychiatry, *by Janet and Paul Gotkin. New York, N.Y., Quadrangle/New York Times Book Co., 1975, 395 pp., $10.95.*

The subtitle of this book reveals its content. This is a detailed account of a woman's experience as a psychiatric patient constructed retrospectively by the former patient and her husband. They acknowledge their bitterness and their intent to attack "a new ever-hungry monster of mental health care." Their audience is the lay public, and their target is psychiatry and psychiatrists.

The story is well written, although sometimes a bit tedious. It conveys the 10 years of intense pain that began for Janet Gotkin when, as a highly successful overachiever, she was unable to tolerate separation from home on entry to a prestigious women's college. She was aware of a profound resentment at attending a school she did not wish to attend; she felt that her life had been a charade aimed at pleasing her parents. Their hopes for her older brother had been completely dashed by innumerable battles that culminated in his flight from the home. All of her parents' expectations were then focused on Janet, who could neither say no nor rebel directly or indirectly.

To this point the story is clinically familiar. Janet's description of the pain she experienced during her year at college makes for compelling reading. She turned to the college counseling service for help; here we meet her first therapist: "Dr. Kurtzman was an ugly man . . . . fat, manicured fingers . . . my first and lasting impression was of a sloppy, sated, lewd old man." He was of no help to her, so she turned to Dr. Wyatt: "Perhaps if he had shown any real interest in me, I might have opened myself a little, . . . but he didn't seem very concerned about my silence or very interested in hearing me when I did speak."

She then took a medical leave of absence from school and was referred to Dr. Berman. He had a 15-minute interview with her and her parents together during which he told Janet's father that he would be away for two months but would see Janet when he got back. Two months later she came to see him. He said, "As you no doubt know, the treatment will be psychoanalysis. You will come five times each week, 50 minutes each session. I will give you a schedule of appointments today. Do you have any questions?" Terror stricken, she obeyed his order to lie on the couch and tell him whatever entered her mind; then she slashed her wrists in his washroom. He brought her parents in immediately, dismissed her as "most unresponsive and uncooperative," and sent her off to the first of many hospitalizations.

All of the psychiatrists Janet met thereafter, with only one dubious exception, are disposed of predictably in this book. There is the "shithead" who was more frightened of her than she was of him. There is "another dull-eyed resident"; there is "the psychiatric resident, a silly-looking young man"; and there is the ward psychiatrist, "a glum-looking man in a well-tailored suit."

Most of all there is Dr. Sternfeld. (All of the names of doctors and hospitals are fictitious in this book to preserve anonymity and, one might suspect, to avoid libel suits.) Dr. Sternfeld was the "eclectic psychiatrist" who, over a period of 8 years, loaded her with huge doses of every psychotropic drug available, prescribed innumerable ECTs, and, in desperation, suggested insulin coma but could not find a hospital that used it anymore. According to the patient, neither he nor she ever recognized that her relationship with him was a precise duplicate of her relationship with her parents. With him she was once more the "golden girl" who lived out his every aspiration while repressing the murderous rage arising out of her dimly felt awareness that she was sacrificing her understanding of her own autonomous, worthwhile self. Dr. Sternfeld cared about Janet and displayed remarkable devotion, persistence, and dedication. He knew about drugs and ECT and made a point of the personal touch, including holding her and suffering with her—like a parent.

The patient perceived Dr. Sternfeld as a controlling, omniscient parent who slowly but surely became increasingly helpless himself in the no-win battle with a daughter whose dependency and rage were more than she could tolerate. No wonder she repeatedly slashed her wrists (as a means of feeling alive) and overdosed, always arranging beforehand to be found out.

After 10 years of suffering, Janet finally took a huge dose of thioridazine, was comatose for 5 days, and emerged with a sense of joy at being alive. In fact, she felt reborn. It was as though she had to die in order to live—death was the ultimate cleansing that enabled her to make the separation from her parents and from her psychiatrist. She effected her own release and, understandably, accepted it as a mystery, a miracle of sorts, and as proof that she had never been ill but only made so by self-serving professionals. For 5 years now she has been entirely well, living the ordinary trying experience of everyday life with her husband, who struggled along with her during the last 5 years of her illness, and with her daughter, who was born after her recovery.

Now that she is well, Janet and Paul Gotkin's bitterness for all of the bad treatment she received takes two channels. One is the total denial that Janet was ever sick. They reason that sickness is something of the body and that to become sick of the mind results from the diagnosis and brainwashing of psychiatrists whose livelihood depends on making certain that patients accept psychiatrists' perverted view of humaneness and humanity. The second channel is the organization of a group called Mental Patients' Resistance, whose task is to "inform the public of the exploitative nature of institutional psychiatry."

This book joins a number of the same genre. Their value often consists in their bringing to the lay public an appreciation of the suffering of the mentally ill. They usually provide information that is to be found in detail only in the psychiatric and psychoanalytic literature and is therefore unknown to the public. It is all to a fine purpose that the public be informed of the agony of mental illness by one who is ready to open herself about her experience; the truth of pain needs no defense. However, the cause of pain requires much more than a self-serving condemnation of all of psychiatry. I suppose that it is possible in a world in which anything can happen that Janet had the misfortune to fall upon a selected group of the worst psychiatrists and the worst private and public mental hospitals. The psychiatrists, psychoanalysts, psychiatric residents, nurses, and aides that I have known

and worked with in all settings have been notable for their efforts to understand and help rather than dismiss and punish. I am not saying that Janet can be all wrong, but all of her possible helpers could not have been so malevolent as she describes them.

It is in Janet's interest to maintain the fiction that the whole cause of her misery lay outside of herself. By institutionalizing the enemy she can achieve even greater distance from herself. The fantasy of rebirth after an extremely serious suicide attempt is not unusual. It becomes, in this book, a remarkable demonstration of the survival value of externalization. It affords a way to make political capital at the expense of a profession and all of its helpers. Once more a large segment of the public is invited to malign psychiatry and its workers. It is too bad that the richness of the writing in this book is entirely in the service of a myth of nonillness made into illness by the cruelty, inhumanity, and avarice of all psychiatrists. Perhaps it is consonant with the times we live in that all difficulties are assigned to the enemy out there, thus disposing of individual responsibility.

JAMES MANN, M.D.
Waban, Mass.

Rypins' Medical Licensure Examinations: Topical Summaries and Questions, 12th ed., *by Arthur W. Wright, M.D., with the collaboration of a review panel. Philadelphia, Pa., J.B. Lippincott Co., 1975, 999 pp., $25.00.*

This old friend of worrisome pre-examination nights has now appeared in its 12th edition. It is a veteran of 40 years on the medical scene, and this edition has been refurbished and updated with four of the chapters rewritten by new authors.

Still divided into two broad areas, basic medical sciences and clinical sciences, the subject matters covered are those most frequently asked in the various licensing examinations. The examinations covered now are not only the various state board exams but also the national board exams and the more recent Federal Licensing Examination (FLEX). Foreign medical school graduates who are required to take the Examination Certifying Foreign Medical Graduates (ECFMG) will find the book particularly helpful. Sample questions are appended to each chapter.

This volume presents a compact, concise, and orderly survey of the several fields of medicine in which one is sure to be examined. Special emphasis is placed on up-to-date knowledge of cell structure and function based on electron micrograph studies, and investigations with the ultracentrifuge are to be found in several of the chapters. The chapter on psychiatry, titled "The Synopsis of the Scope, Goal, and Content of Psychiatry," is presented by Howard P. Rome and Gordon Moore of the Mayo Clinic.

There is a chapter on public health and community medicine, which seems particularly important in this day of community involvement and with the possibility of national health insurance in the offing. The chapter covers material that was not taught to older clinicians; it just might interest everyone.

One can get an idea of the general medical qualifying examinations by reading the first chapter of the book, which is authored by Dr. Wright. Types of examinations and the constitution of the various licensing bodies are discussed here. The FLEX is certainly new to older graduates; it was not introduced until 1968. In addition, examples of various types of questions, including multiple choice and essay, are to be found in this chapter.

In the entirely new segment on behavioral science, written by John Paul Brady and Fred and Mary Ann Strider, a whole host of subjects is considered: genetics; biochemical aspects of behavior; the life cycle of learning; society, man, and the physician; and theories of personality development comprise a partial list. All of these subjects reflect modern medical thinking and give evidence of its involvement in the broad spectrum of human events.

Although no one will require the reading of this book in order to pass medical specialty board examinations, anyone who contemplates taking any medical licensing examination would do well to keep it handy and assimilate what it has to offer. The work evokes a bit of nostalgia as we think back to what we specialists used to know about the various elements of general medicine and brings forth regret about what we have forgotten. Anyone interested in recalling things he was taught years ago and learning the new findings that have been added to medical lore will find this presentation most interesting. The fact that one can read it without the threat of an examination hanging over him will enable him to savor it even more.

F.J.B.

An MMPI Handbook, Vol. II: Research Applications, revised ed., *by W. Grant Dahlstrom, George Schlager Welsh, and Leona E. Dahlstrom. Minneapolis, Minn., University of Minnesota Press, 1975, 567 pp., $25.00.*

For those who enter into any of the numerous areas of research to which the Minnesota Multiphasic Personality Inventory (MMPI) may be applied, this book is the master key. It is the second part of a two-volume revision of *An MMPI Handbook: A Guide to Use in Clinical Practice and Research*, which was originally published in 1960. The first volume of this revision, titled *Clinical Interpretation*, gathered all of the important information about methods and procedures relevant to the interpretation of the test. This second volume is a data bank that contains all of the important knowledge pertaining to the research use of the MMPI that has accumulated since the publication of the original handbook.

This second volume, like the first, has the virtue of being useful to beginning MMPI students as well as to experts because it can save countless hours of searching the literature in an area one plans to investigate by providing complete bibliographies. It also introduces all of the important ideas about applying the test to a particular area of research. For sophisticated MMPI users this is a reference book.

The book is well organized and clearly details the important research uses of the MMPI, e.g., in recognizing emotional disturbances or in predicting the presence of some behavior or attribute of psychological functioning. It also compiles the recent data and ideas for applying the test to the investigation of medical problems and describes its applications to the system of criminal justice and to educational and vocational questions. The authors also review the important literature concerning studies in which the test has been incorporated into experimental investigations of personality and behavior. They discuss the major sources of variance in the test and describe its usefulness in treatment evaluation.

The great usefulness of the MMPI lies not in predicting the old nosology (as it was originally constructed to do). The test

is useful because of all that has been learned about it over the years. It is useful in the effort to recognize a variety of traits, qualities, and complex patterns of personality and behavior. The 10 clinical scales of the MMPI have become indices of numerous characteristics other than psychiatric diagnoses. Beyond the 10 clinical scales and 3 validity scales, which are described in the first volume, this second volume includes the items and directions for scoring the items for the 455 special scales that have been generated from the original item pool. These scales are indices of a variety of characteristics—from promiscuity to success in baseball and from headache proneness to pharisaic virtue.

Both volumes of *An MMPI Handbook* provide access to the full usefulness of the MMPI. They bring all of the important ideas into one publication. The second volume includes a bibliography of over 6,000 significant references to the MMPI through the end of 1973.

DAVID F. BERRY, PH.D.
Hartford, Conn.

Evaluating Treatment Environments: A Social Ecological Approach, *by Rudolf H. Moos. New York, N.Y., Wiley-Interscience (John Wiley & Sons), 1974, 377 pp., $15.95.*

This is a carefully developed, highly useful book that introduces the reader to an extensive collection of techniques for the evaluation of mental health treatment environments. The book and the technical approaches to evaluation it describes are the outgrowth of research and investigations carried out in a number of quite different kinds of inpatient and community settings in the United States and abroad.

Moos and his associates see themselves as following the tradition of such earlier social psychologists as Stanton and Schwartz, whose descriptive studies of inpatient treatment settings first pointed to a relationship between changes in caregiving ecology and changes in patient behavior. Moos has gone beyond the empirical observations of the social-behavioral scientist to design tools that will measure the often divergent points of view of the participants in the therapeutic process—both patients and staff.

How are treatment settings perceived by patients and how are they perceived by staff? What are the implications for effective treatment of various patterns of patient-staff perceptual dissonance and consonance with regard to the treatment environment? What are the implications for both the immediate treatment situation and for the patient's well-being after discharge from the hospital? How can the evaluation process itself be used as a tool to help caregivers make the necessary changes that will render their programs more effective? Moos suggests a process and gives examples of situations in which his group has successfully used evaluation feedback to produce constructive change and more effective clinical programs.

The book appears to be written primarily for the behavioral science researcher who is interested in studying what makes mental health treatment environments work so variably in different patient populations. However, it has something useful to say to other groups as well. The mental health administrator and program developer will find the approaches to evaluating the ecology of the treatment environments of practical help in establishing more effective treatment environments. Those concerned about questions of the cost effectiveness of various ways of organizing the treatment setting will find the book helpful in unraveling some of the professional mystification of milieu therapy and in developing guidelines or criteria for program operations.

In an increasingly cost-conscious age, the ecological approach implicit in this book suggests ways of using the powerful effects of treatment milieus by means that are more precise and systematic and that strengthen the art of treatment and clinical management with science.

JEROME A. COLLINS, M.D.

Psychotherapeutic Approaches to the Resistant Child, *by Richard A. Gardner, M.D. New York, N.Y., Jason Aronson, 1975, 377 pp., $15.00.*

As any psychiatric trainee knows, the learning of child psychiatry is an unsatisfactory business. The journals and texts are full of case descriptions and theory, but there is a striking lack of information on how to use the technology of child psychiatry.

One of the results of this defect is that the techniques of child psychiatry have very little generalizability to closely related fields, e.g., general psychiatry, pediatrics, education, and child welfare. Too many child psychiatric techniques have the unfortunate and autistic definition of "activities done by a child psychiatrist." The specialty remains arcane, and overworked child psychiatrists are distressed at the degree to which other professionals seem unwilling to work psychotherapeutically with children.

Among those who have attempted to fill in this defect, Richard Gardner has made a number of excellent contributions. His mutual storytelling technique, which makes use of videotape or a tape recorder, has been a highly practical therapeutic device, and his books for children and parents on divorce and minimal brain dysfunction have eased the therapeutic tasks of working with these problems. His most recent book, *Psychotherapeutic Approaches to the Resistant Child*, is no exception. It is particularly valuable for those who wish to acquire or expand child psychotherapeutic skills. This does not mean that the book is not useful for the experienced child psychiatrist—it is—but it will be of even greater interest for trainees, pediatricians, social workers, and others who wish to learn simple yet effective ways of communicating and working with school-age children.

One of the greater difficulties faced by the trainee and the inexperienced professional is to decide which aspect of a child's behavior to focus on. When is a game just a game and when is it symbolic of the child's problems? When is the aggression of toy soldiers indicative of intrapsychic or family conflict and when is it simply an expression of play?

One of Gardner's greatest contributions is his creation of simple and semi-structured games that provide a means of eliciting children's verbal fantasies. In his games the therapist has an opportunity to listen to fantasy material on a regular basis instead of irregularly, as in nonstructured play therapy. This provides a means of obtaining verbal content and, more importantly, a means of focusing the therapist's attention on process—the patterns of perceiving, processing, and coping that are essential to understanding the child's behavior and relationships at home, at school, and with peers.

From a theoretical perspective, Gardner's techniques are primarily oriented toward the psychology of the ego. Although his theory is broadly psychoanalytic, the techniques he has developed illuminate ego function with special clarity.

This book would have been even better if the underlying

theory had been explicated more fully. In particular, I was frequently reminded of Anna Freud's classic, *The Ego and the Mechanisms of Defense* (1). For child psychiatrists in particular, Gardner's book should be read with Anna Freud's. Gardner's extensive clinical examples provide excellent documentation of the defense mechanisms she describes, in particularly denial in fantasy and denial in word and act.

The next question for the inexperienced therapist is, What do you do with this information once you've got it? Gardner's contribution to this problem is one of the rules of his storytelling games—the therapist gets a chance to make up his own stories. This has a number of major practical implications. It gives the therapist a chance to select themes from the child's productions and to feed back his own understanding (or lack of it) of what the child has said. It also gives the therapist an opportunity to create modifications and outcomes that offer improved adaptive solutions for the child and gives the therapist noncritical ways of challenging the child's defenses. Throughout the clinical vignettes one can see Gardner challenging his patients' use of magical and omnipotent approaches to problem solving. In his stories he tells his patients that practice and effort are required to achieve desired goals, that trying is necessary to success, and that children who do not learn how to develop personal, social, and work skills are going to be unhappy and have problems.

Finally, the value of Gardner's ego psychology techniques is that they are fun. Children like the games, including seeing or hearing themselves on video or tape, and therapists like playing them. They offer the therapist expanded opportunities to be creative and to make use of his own unconscious, sublimations, and adaptive skills in a format that can be channeled and titrated according to the patient's needs. Thus the play and the work of child psychotherapy are linked together according to the level of the child's development and the therapist's skill and experience. Professional growth and development can occur as an integral part of psychotherapeutic practice.

In summary, this book, although short on theoretical linkages, is a major contribution to applied psychotherapeutic work with children. In my opinion, it should become a standard text for teaching technique for all of the child professions.

Neurology of Infancy and Childhood, *edited by Sidney Carter, M.D., and Arnold P. Gold, M.D. New York, N.Y., Appleton-Century-Crofts (Prentice-Hall), 1974, 195 pp., no price listed.*

This monograph consists of a well-organized series of chapters by different authors dealing with all of the disease categories commonly involved in the nervous system during infancy and childhood. It is presumably designed to provide an easy and practical source of information for the clinician who is a nonspecialist in neurology and who wants guidance regarding clinical management of a particular problem. The monograph is successful in this regard. Each chapter is also strengthened by a well-organized list of references.

As is so often the case, one can perhaps fault this book on its lack of homogeneity as a result of multiple authorship, but this does not detract from its usefulness. It is therefore recommended for physicians in fields allied with neurology who have occasional contact with problems in this area, but it is not designed as a reference text for the neurologist or the neurosurgeon.

ARTHUR A. WARD, JR., M.D.
Seattle, Wash.

Female Sexuality and the Oedipus Complex, *by Humberto Nagera, M.D. New York, N.Y., Jason Aronson, 1975, 139 pp., $10.00.*

This addition to the burgeoning literature on female sexuality is flawed because it fails to integrate recent advances in our knowledge in this area and relies too heavily on ill-defined and questionable concepts. Dr. Nagera's schematization of the female Oedipus complex holds that, in contrast to boys, who proceed directly from the anal to the oedipal stage, girls experience a phallic-oedipal stage. Dr. Nagera fails to consider the evidence that both boys and girls experience a phallic stage and that this stage is associated in both boys and girls with a narcissistic investment in the entire body at a time when the genitals are becoming the dominant erotogenic zone.

According to Dr. Nagera, in her phallic-oedipal phase the girl experiences her clitoris as a penis and her mother as the object of her libidinal investment. This reverses in the oedipal phase, when the father is sought as the object and the mother is negatively invested. To accomplish this, the girl has to renounce their longings for the mother. As we know and Dr. Nagera confirms, the choice of object may vary and accounts for the constellations referred to as the positive, negative, and inverted oedipal complexes.

Variations in object choice as well as in the final outcome of the Oedipus complex and the female's sexuality and psychology (a distinction that is blurred by Dr. Nagera) are determined by the complex interaction of the biological strength of the girl's drives, the maturation of her ego, and the experience that influences her fantasies about genitalia and her attitudes toward activity, passivity, masculinity, and femininity.

Dr. Nagera's views of female sexuality are misleading because he fails to include observations that do not support his assumptions. His assertion that clitoral masturbation is phallic and that the clitoris has to be renounced if femininity is to be established is contradicted by evidence that the clitoris is an erotogenic zone that is only sometimes perceived as a substitute for a penis and that, rather than renouncing it, the female has to incorporate it into her sexual experience.

Dr. Nagera's equation of femininity with passivity and masochism is also very questionable. The normal female does not seek pain. Rather, she accepts the pain associated with some female functions such as defloration, menstruation, and parturition as the inevitable accompaniments of some of her experiences as a woman. To describe the behavior of women as passive is inaccurate. Homemaking and child care require a great deal of activity, as do many of the other things that women do. It is true that the sexual behavior of women is different from that of men, but this difference is more appropriately described as receptive than passive. Gratifying

intercourse is not an experience in which something is done to a woman; it is one in which she actively participates.

Dr. Nagera's case material illustrates some of the weaknesses of his theoretical formulations. The masochism of some of his patients is pathological and related to unresolved oral and anal issues. Although he acknowledges that their masochism is excessive, he states that a certain amount is necessary for normal femininity. The pathological aggresivitv of some of his patients is not determined by their unwillingness to renounce the pleasure of their clitoris but to their anger and hatred, which are related to many factors, including experiences in which men were overvalued and women were humiliated and demeaned.

We have a great deal to learn about the psychology of women and the marked tendency of societies throughout history to undervalue women (albeit ambivalently). To better understand these phenomena, we need more detailed observations of the influence of anatomical and biological factors on fantasies and other psychic representations related to maleness and femaleness and the interaction of these factors with social and economic forces. Dr. Nagera's contribution tends to retard rather than advance our knowledge because of his failure to critically examine some of the concepts he invokes.

REBECCA Z. SOLOMON, M.D.
Hartford, Conn.

Prometheus Revisited, *by William H. Sheldon, Ph.D., M.D. Cambridge, Mass., Schenkman Publishing Co., 1975, 248 pp., no price listed.*

Those familiar with the name of William Sheldon should be informed of the basic difference between his previous important studies on the human constitution in relation to clinical matters, such as *Varieties of Delinquent Youth* (1), and the present volume. Published almost 40 years ago as *Psychology and the Promethean Will*, this book is provocative, pointed, exciting at times, and frustrating. Written in an incisive, aphoristic style, it conveys the strong message of a physician who, disenchanted with today's state of civilization, temporarily renounces the role of the scientist to take over that of philosopher and theologian.

Underlying the many points brought up in the book is the main theme of Prometheus (i.e., forethought) versus his brother Epimetheus (i.e., afterthought)—the daring and radical versus the conservative and organizational. For Sheldon, the ultimate function of religion is to harmonize Promethean and Epimethean urges by attempting to integrate affect with cognition. Unfortunately, in his view, religion is hindered by the pitfalls of power, money, and sexual morality. Worst of all, the conflict between the Promethean and Epimethean trends contributes to the rise of what Sheldon terms "waster personalities," i.e., the many people affected by human disorientations who give up the use of their forebrain and become addicted to advertising and slogans. As a remedy to this rather gloomy situation, Sheldon advocates a fusion of religion and social psychiatry. He then proceeds to discuss the main tenets of five dimensions (or "panels," as he calls them) of feeling and awareness: 1) material relationships, 2) social interrelationships, 3) reproductive relationships, 4) need for a humanistic religion, and 5) aesthetic fulfillment. He then discusses clinical issues in regard to each of these panels. Throughout the book the criticism of psychoanalysis and of its founder is pervasive and stringent. At times the criticism is convincing, e.g., the attribution to the mind of an unconscious consciousness is a logical absurdity. At other times the criticism appears unfounded, for example, the author's blending of Freud and American psychoanalysts and his irony about women psychoanalysts. At the root of Sheldon's opposition to psychoanalysis may very well be his devotion to Jung, to whom he publicly acknowledges his debt and from whom he borrowed the concepts of persona and anima.

Sheldon's criticism of our present institutions is sometimes hard to accept, notably, his criticism of nursery schools, children's clinics, and child aid societies, all of which he finds guilty of producing "normal," socialized, extroverted children, i.e., potential wasters. Sheldon's comparison of his Promethean and Epimethean types with his typological models of endomorphic (viscerotonic), ectomorphic (cerebrotonic), and mesomorphic (somatotonic) are hard to follow, especially in view of the fact that most individuals are a mixture of these types.

On the other hand, there are appealing points in this book, such as the emphasis on the primeval character of the female in comparison with the male and Sheldon's statement that, in contrast to the modern tendency to push young people into mature roles, many children need more time to mature sexually and in other ways.

Has the author succeeded in his endeavor? Will he be able to convince the reader of his theses or will the effect mainly elicit nostalgia for things past? Whether he is quixotic or prophetic, Sheldon's candor in this book has appeal. Even if he is a voice in the desert, it is a voice that needs to be heard once in a while.

GEORGE MORA, M.D.
Poughkeepsie, N.Y.

Psychiatric Aspects of Neurological Disease, *edited by D. Frank Benson, M.D., and Dietrich Blumer, M.D. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1975, 307 pp., $17.50.*

A basic tenet in nineteenth-century thinking was that the brain is the organ of the mind. This implied a special relationship between psychiatry and neurology and resulted in the hybrid specialty of neuropsychiatry. In the early part of the twentieth century this special relationship loosened; it was even denied. Emphasis shifted to the learned aspects of behavior and to interpersonal and social forces as determinants of aberrent behavior. In more recent years the tide has turned again as the result of a deeper and broader understanding of the neuronal and biochemical determinants of behavior. For example, certain neuroleptic drugs not only ameliorate schizophrenic psychosis but can permanently derange the metabolism of biogenic amines, leading to persistent dyskinesias; asymmetries of function in the cerebral hemispheres may result not only in dramatic disturbances of language function with left-hemisphere lesions but in more subtle and less well understood impairments in recognizing stimulus equivalence with lesions in the right hemisphere.

The editors of this volume offer a multi-authored review of clinical problems in the traditional borderlands of neurology and psychiatry. A brief listing of the topics will suggest the breadth of coverage to the potential reader. The volume opens with a brief but lucid review by Norman Geschwind that emphasizes why psychiatrists must know the neuroanatomy of behavior. Lipowski then proposes a reclassification of the so-called organic brain syndromes. Three chapters address themselves to the problems of diagnosis and treatment of dementia, and three other chapters address the difficult questions of defining the deficits in behavior with lesions of the frontal and temporal lobes and the much-debated but still poorly understood relationship between temporal lobe epilepsy and personality disorders. C. David Marsden and colleagues provide a lengthy and well-documented review of the problems of spontaneous and drug-induced movement disorders in psychotic patients. The succeeding chapter considers dementia and episodic affective disorders in Huntington's chorea.

This is a well-planned and well-executed volume that should be read by all residents in psychiatry as well as by psychiatrists preparing for Boards and those exposed to a broad spectrum of psychiatric disease. Neurologists, although more often exposed to the problems presented here, will likewise find a great deal of interest in the book.

I find only one major fault in this volume, and the publishers are to blame. For some reason that defies comprehension the table of contents lists the chapters but not their page numbers. The reader looking for a particular chapter must thumb through until, by chance, he eventually finds the opening pages. This bizarre decision surely merits the now-defunct Rowan and Martin Flying Finger of Fate Award.

DAVID D. DALY, M.D.
Dallas, Tex.

The Psychobiology of Depression, *edited by Joseph Mendels. New York, N.Y., Spectrum Publications (Halsted Press, John Wiley & Sons, distributor), 1975, 172 pp., $15.00.*

This book deals with an area of great importance to psychiatry, yet it leaves me with a feeling of disappointment. The disappointment is not a result of any fault in the book. Rather, it is caused by the honest reporting of hopes yet to be fulfilled.

Approximately 20 years ago two accidental observations of great value were made: reserpine could induce depression; and iproniazid, a monoamine oxidase inhibitor, seemed to bring on euphoria. These findings had far-reaching clinical implications. With the addition of the tricyclic antidepressants and lithium salts, an important step forward in the treatment of affective disorders was accomplished. Besides their clinical value, there were additional results of these seminal findings: an amine hypothesis was formulated to help conceptualize the biology, biopathology, and pharmacotherapy of affective disorders; and a large cadre of dedicated investigators focused their energies on testing, extending, and revising that hypothesis.

Dr. Mendels, one of the leading investigators of the hypothesis, edited this "state of the art" volume, which explores the testing of the amine hypothesis, the implications of it, its relationship to other biological issues, and problems of research. The book presents many fascinating issues. It deals with such new areas of investigation as postsynaptic events, alterations in cell membrane function, previously unstudied metabolites, and the role of neuroendocrines. The book also discusses the genetic implications of the work and evaluates such techniques of investigation as the study of red blood cell and platelet function and sophisticated clinical strategies. The many facets of a monumental research effort are revealed by the various authors.

What emerges from all this work? There is a multitude of interesting findings, but validation and significance are often lacking. A number of worthwhile results, however, are evident, e.g., patients with affective disorders can now be classified in terms of response or nonreponse to specific drugs. This finding not only has clinical value but also improves our understanding of the biological basis of affective disorders. The genetic part of the theory has also been developed. However, the research itself has not led to great clinical advances. Theoretically, the original amine hypothesis has not been confirmed. At best, it survives as a partial formulation of numerous complex factors.

Our knowledge of biological aspects of affective disorders has been enhanced by many bits of knowledge. Some of these may become cornerstones for significant advances. However, the work of the last 20 years has not led to an integrated theory, nor have striking new clinical strategies emerged. To quote Dr. Mendels, "Much of the work which has been done remains controversial and needs elaboration and expansion. New concepts must also be sought."

NORMAN TABACHNICK, M.D.
Sepulveda, Calif.

World History of Psychiatry, *edited by John G. Howells, M.D., D.P.M. New York, N.Y., Brunner/Mazel, 1975, 728 pp., $25.00.*

This volume presents a country-by-country summary of psychiatric history. Most of the contributors are academic or institutional leaders in the countries they report on, and there is a lot of inevitable repetition as well as some signs of national pride (e.g., the writers from many countries suggest that witch trials were more common in other countries than in their own). Recent events are generally regarded as the most propitious, even by the editor, who deplores the tendency. Understandably, the most outstanding chapters are the work of historians, notably Veith on the Far East, Simon on ancient Greece, Margetts on early Canada, Fischer-Homberger on Germany and Austria, and Mora on Italy. The bulk of the other chapters are little more than accounts of institutional and legal changes. Nevertheless, even the most summary chapters give a sense of psychiatric development as it has occurred in sharply different times and places, especially the fascinating chapters on Africa and the Arab countries.

Several impressions from this book strike me. There have been few fundamental discoveries in psychiatry, and the times of their introduction have varied considerably. Psychiatry appears to have been a development of the last 20 or 30 years in many countries. However, the order in which changes appear has not varied very much. For example, mental hospitals are established, then stabilized, then turned toward a therapeutic milieu, and then toward the community. General hospitals are gradually involved in psychiatric work, psychoanalysis is introduced, and then a sociological approach is taken.

Expansion in psychiatry is worldwide, but child psychiatry lags in almost every country. There is less dependence on German and English training and more on centers in North

America. Ironically, as the prestige of dynamic psychiatry falls in the United States it appears to be advancing almost everywhere else. It would be tragic if the United States should have less and less of what other countries seek here because we have come to resemble the German and English centers they leave behind.

Little good is written of psychoanalysis in these chapters, despite the general claim that it is continuing to grow in countries where it is not forbidden for religious or political reasons and the fact that it is occasionally recommended for therapists. Mental retardation receives the cursory attention one has come to expect from psychiatrists; its institutional aspects alone are taken up, and only briefly.

I believe that this is the first world history of psychiatry to be assembled. Indeed, it appears to be the first time the psychiatric histories of a number of countries have been reviewed at all. This is a volume well worth publication and well worth reworking every several years.

LESTON L. HAVENS, M.D.
Boston, Mass.

Humanizing the Psychiatric Hospital, *edited by Alexander Gralnick, M.D. New York, N.Y., Jason Aronson, 1975, 283 pp., $10.00.*

This volume is a collection of papers reflecting the program at High Point Hospital in Port Chester, N.Y. Sixteen of the 19 papers have been previously published. The institution is described as a psychoanalytically oriented hospital serving adults and adolescents, most of whom are chronic schizophrenic patients. The papers are grouped into three categories: clinical theory, clinical applications, and clinical research.

The first portion of the book is a very human account, largely in a personal style, of the attempts of Dr. Gralnick and his medical staff to build and develop a humane and clinically effective hospital in the private sector. In the second portion, there are several papers describing various clinical problems encountered in the hospital and the sincere and skillful efforts of the staff to deal with them. The research papers in the third part of the book include a frank appraisal of the results of the program, which are often disappointing, and an excellent study of the impact of staff attitudes on treatment effectiveness.

The theme of humanization that is intended to unify the book does not appear to be exhaustively addressed. Although there is no doubt as to the humane qualities of the professional staff, the book does not satisfactorily deliver on its implied promise to specify the unique manner in which this hospital designedly offsets the alienating and dehumanizing experiences that its patients have undergone in their troubled pasts. In fact, the book describes a highly unified staff functioning in a structured manner that may border on benevolent authoritarianism in dealing with patients.

The implication seems to be that the patient's experience in this humane, highly ordered "family" will serve as a significant corrective emotional experience to offset the psychotogenic effects of prior life outside of this hospital. Sadly enough, the follow-up studies candidly presented in the third portion of the book fail to convincingly support this thesis. Indeed, it is highly questionable that six months of hospitalization—the seldom-achieved optimal period cited in the book—can be expected to significantly reverse the noxious impact of the past lives of psychotic patients, even though family therapy, also emphasized in the book, is concurrently provided.

It is with regard to the place of inpatient hospitalization in the total necessary spectrum of therapeutic experiences that the volume is critically inadequate. Community psychiatry is depicted as a kind of enemy of the proprietary psychiatric hospital, although any responsible community psychiatry program regards the specialized psychiatric hospital as a valuable portion of the total spectrum of services, not an antedeluvian relic to be totally eliminated or replaced. The prime justification for community psychiatry seems to be the guarantee of an articulated array of clinical and associated services to the mentally ill. This is certainly a necessary improvement over the discontinuity of isolated institutions carrying out their programs, however humane and clinically sound, with little or no acknowledgment that vital services to the patient must go beyond what is carried on within the protective confines of the hospital.

Dr. Gralnick and his valiant staff need not fear the incursions of community psychiatry if their concern for humanization of patient care leads them to consider the patient's total therapeutic experience in the community and to link arms with community psychiatry rather than set themselves at odds with it.

HARRY R. BRICKMAN, M.D.
Los Angeles, Calif.

Progress in Community Mental Health, Vol. III, *edited by Leopold Bellak, M.D., and Harvey H. Barten, M.D. New York, N.Y., Brunner/Mazel, 1975, 332 pp., $15.00.*

The volume does an excellent job of reviewing the current state of community mental health theory and practice. As do all such compendiums, it varies in quality, but all of the contributions are useful.

The book is divided into four sections: The Changing Scene; Developments in Community Mental Health; Some Special Programs, and Neglected Populations; and Evaluation and Research. The chapter on "The Catchment Area Concept," by Gary L. Tischler and associates from the Department of Psychiatry and Epidemiology and Public Health and the Institution for Social and Policy Studies at Yale University, is an excellent discussion of a very controversial subject. The chapter by H. Richard Lamm on "Treating Long-Term Schizophrenic Patients in the Community" is a clearly written exposition that contains a great deal of hard-won clinical wisdom.

The most outstanding chapter in the book is that by Jack Zusman, "Program Evaluation and Quality Control in Mental Health Services." He says,

> The importance and universal usefulness of program evaluation efforts are so far among the great myths of mental health and other human service fields. . . . While huge sums of money have been spent to evaluate service programs, individual efforts have been widely scattered and often undertaken by individuals with relatively little preparation. Impact of these programs appears to be close to zero. . . .
>
> Few of the proponents of program evaluation have addressed the fundamental question of why program evaluation studies *should* have an effect on practice. In a world where financial and professional rewards go to the administrator of the big agency with good public rela-

tions, where the consumer is unable to judge the quality or value of the clinical service he gets, and where professional ethics are becoming progressively weaker, where is the force that can be expected to move an agency away from providing poor or useless service toward good and effective service? (pp. 233, 234)

From this highly skeptical beginning, Dr. Zusman goes on to discuss the various categories of evaluation activity, such as effort, system, structure, process, and outcome evaluations. He also examines evaluations as a political process and talks about undertaking an evaluation study from the administrator's point of view. He examines cost, administrative issues, and the evaluator's professional role.

Overall, this book can be recommended without reservation for both the advanced practitioner and the student of the community mental health undertaking in the United States.

H.G. WHITTINGTON, M.D.
Denver, Colo.

Mental Hospitals: A Study in Organizational Effectiveness, *by Clagett G. Smith and James A. King. Lexington, Mass., Lexington Books (D.C. Heath and Co.), 1975, 181 pp., no price listed.*

For many years mental hospitals have been the center of controversy, particularly over the question of whether or not they really help their patients. Many authors have written that mental hospitals do more harm than good. Despite the many publications on the subject, little solid research has been accomplished. However, the authors of this book present a systematic organizational study of the mental hospital.

The research operations were carried out over a five-year period. A total of 18 hospitals were selected to represent the national population as nearly as possible. The size of the hospitals varied from a small 275-bed hospital to two of the largest in the country (both had more than 11,000 patients).

Some of the areas covered in the authors' analysis include measurements of hospital effectiveness, work environment of the whole staff, communication and coordination, hospital goals, and decision-making processes. A very impressive aspect of the research is the fact that discharged patients were contacted and interviewed to assess their current mental status and community adjustment. By this method, some measure of how well hospitals were meeting the goal of successful rehabilitation was made. This aspect of research is all too frequently ignored when treatment goals are evaluated.

The authors found that such organizational factors as goals, structure, and administrative behavior did not have the direct effects they had originally expected. However, they state that with proper use of both organizational and administrative processes a truly therapeutic community can be realized.

This book has a message for all mental hospital workers—from the chief administrator to the ward personnel. Its findings should be made known to legislators as well because the authors' unmistakable message is that with adequate planning and funding, mental hospitals can be made to function efficiently for the benefit of the people they seek to help.

A major criticism I have of this book is that it is very difficult to read because of the tremendous amount of data presented. Many readers may feel so overwhelmed with the scientific material that they may not stay with the book to reach the conclusions. However, I would emphasize that if one expends the necessary time and effort, reading this book will be a rewarding experience.

GEORGE W. BARTHOLOW, M.D.
Omaha, Neb.

Collusion for Conformity, *by Andrew Slaby, M.D., M.P.H., and Laurence Tancredi, M.D., J.D. New York, N.Y., Jason Aronson, 1975, 203 pp., $10.00.*

This book sets out to analyze the role of nonconformity in the culture of the United States. The authors seek to examine the structure, nature, and rationale of the various institutions and mechanisms devised by society for controlling individual behavior. Slaby and Tancredi review the issues of privacy, drug use, sexual behavior among consenting adults, suicide, and euthanasia. In the final two chapters they discuss conduct affecting others and give their conclusions. They advise better societal control mechanisms for minimizing harmful behavior by the individual toward others as well as for allowing the individual the optimal degree of freedom for happiness, creativity, and social progress.

The authors take a utilitarian ethical position; shifts in society's attitudes toward drug use, sex, and euthanasia are interpreted in terms of socioeconomics. Thus society's current awareness of the need for zero population growth promotes tolerance for homosexuality, contraception, and abortion, which were all once regarded as seriously deviant behaviors subject to strict control by the church, psychiatry, or the law. They argue strongly for full disclosure of the real issues behind societal control of deviant behaviors.

> The critical point is that control of behavior, particularly that which can be considered victimless behavior, should be clearly for policy reasons rather than reasons that result in the distortion of the ends to be achieved by [such] social systems as psychiatry and morality. (p. 201)

Slaby and Tancredi also advocate what they call a "balancing test":

> What is really required at this time is a test for balancing the individual's rights of privacy and freedom against the harm or potential harm that such behavior would have to the society. Such a balancing should include objective evidence of the harm that might be induced by certain behaviors. (p. 70)

The authors do not define how such a test should be constructed, who should administer it, or how the results should be applied.

Their arguments tend to be weighted heavily toward the liberal position in their discussions of the right to die and the right to privacy. In pointing out the "tremendous social benefits" arising from "maximum privacy," for example, they appear to overlook completely the harm caused by such secret societies as the Ku Klux Klan and the Weathermen. In their conclusion about euthanasia they state,

> It might be expected that as we become tacitly aware of the needs of society that some modes of active euthanasia, such as administering a lethal dose to a patient who consents to euthanasia, or even possibly the elimi-

nation of grossly deformed children, might become societally condigned [sic]. (p. 174)

This sounds uncomfortably reminiscent of the rationalizations used by Nazi Germany to eliminate those judged unfit and unworthy.

The style of the writing is cumbersome due to the authors' preference for long sentences. Pope's admonitory couplet would be fitting here:

Words are like leaves; and where they most abound,
Much fruit of sense beneath is rarely found.

Besides the professorial sentences that weary the reader, the authors repeat throughout the book the hackneyed terms "in effect," "of course," "in fact," "by the same token," and "nonetheless." They also reveal carelessness when they say that "Thou shalt not kill" is the fifth Commandment (p. 156); it is the sixth. Finally, the publisher should fire the proofreader: there were obvious errors on pp. 40, 41, 44, 46, 50, 80, 90, 96, and 104, at which point I stopped looking.

FRED B. CHARATAN, M.D.
New Hyde Park, N.Y.

A Child Is Being Beaten: Violence Against Children, An American Tragedy, *by Naomi Feigelson Chase. New York, N.Y., Holt, Rinehart and Winston, 1975, 225 pp., $8.95.*

In considering child abuse in a clinical setting or a discussion of a book, one cannot avoid noting that feelings of such intensity are stirred up that both the helplessness and the wish to lash out at the institutions, systems, and individuals charged with the responsibility of protecting children are made understandable.

Ms. Chase, who is a free-lance writer, was alternately depressed, horrified, and fascinated by the idea of a book on this subject; she clearly experienced what almost all of us feel when confronted with this phenomenon. Her response is not atypical either: she lashes out at those charged with protecting children. Being human, readers are likely to feel the lashing is deserved until it comes to their own institution, discipline, or profession.

Chase considers the economic system to be responsible for the institutionalization of child abuse. She states that children are neglected as a matter of social policy "even if that policy is due to lack of resources." She is scornful of early reformers and of present-day individuals and agencies that work with these children and their stressed families. A newspaper that launched a sensational and somewhat hypocritical crusade after the death of a child does not fare any better in her opinion. Bungling courts, indifferent legislators, a foster-care system that does not afford a child the love and care that is needed, and overloaded social agencies offer no solutions. Chase also derides individual treatment because, in her view, the real problem is the social neglect of all children, particularly poor and minority children.

Chase draws conclusions from her study and makes recommendations for the provision of the following: jobs for all, because the joblessness of the father and his absence from home is an important cause of child abuse; compensation for women who work at home as a way of reversing the downgrading of the role of the mother; good child-care arrangements for women who work outside of the home; decent housing; income redistribution; free health care; education in infant care; family education; an expanded day-care system; family help centers; prohibition of corporal punishment in all schools and institutions; and free abortion on demand (despite the fact that she equates abortion with infanticide).

These recommendations are humane, but some of them would encounter insurmountable opposition. All of them come at a time of major retrenchment in publicly supported social, economic, and health programs. To what use can recommendations be put if they cannot be implemented? Furthermore, Chase is adamant that child abuse is a social problem; one wonders why she finds it so difficult to view it as both a social problem and a problem that occurs in individuals. This book presents us with the curious phenomenon of a very negative view of psychoanalysis from an author who repeatedly cites evidence from psychoanalysts and their works, not to mention that the title of the book is the title of one of Freud's most famous papers (1).

1. Freud S: "A child is being beaten": a contribution to the study of the origin of sexual perversions (1919), in Complete Psychological Works, vol XVII. Translated and edited by Strachey J. London, Hogarth Press, 1955, pp 175–204

JACOB SWARTZ, M.D.
Boston, Mass.

Zen Meditation Therapy, *by Tomio Hirai, M.D. Tokyo, Japan, Japan Publications (Elmsford, N.Y., Japan Publications Trading Co., distributor), 1975, 103 pp., $3.25 (paper.)*

Psychophysiology of Zen, *by Tomio Hirai, M.D. Tokyo, Japan, Igaku Shoin, 1974, 141 pp., no price listed.*

These two small books complement each other. *Zen Meditation Therapy* is a rather low-pitched presentation of the neurophysiological and psychophysiological aspects of Zen. It supplies answers about Zen meditation in a Western scientific frame of reference. In an elementary manner, it covers many issues that may bore anyone who has already studied the beneficial effects of true mental and physical relaxation. It presents Zen (Zazen) as a therapeutic process rather than a religious experience and aims at providing knowledge of the techniques of reaching the ideal mental state of meditation. This ideal state is defined in terms of the type of brain wave activity, cardiac rate, respiratory rate, and galvanic skin response existing in this condition.

The reader will learn many new Japanese terms, such as "Hishiryo," the state of concentrating without thinking, the state of Zen enlightenment. Hishiryo is presented as the goal for the Western meditator. Our built-in cultural resistance to Zen because of its Eastern religious ties is approached in this brief book; it tries to make Zen more scientific and less religious and thus more acceptable to the Western reader. The book is easy to read and is recommended to the physician interested in exploring and/or developing a technique for applying relaxation and learned autonomic control therapeutically.

Psychophysiology of Zen is an attempt at a more scientific presentation of the subject, an effort to make it appealing to the Western scientific mind. Under such headings as "Physiology of Zen Meditation," "Results of Stimulation Experiments in Zen Meditation," and "Changes in Respiratory Functions During Zen Meditation," the author presents sum-

maries of research data accumulated. The very critical will find many questions unanswered in these chapters; the inquisitive will find many stimulating answers.

There is a chapter on "Zen Meditation and Feedback Training, or the Voluntary Control" that looks briefly at Zen meditation versus biofeedback. This chapter encapsulates the differences between the Eastern and Western approaches to relaxation and autonomic control as a therapeutic process: "The start of the study is different in East and West, but the results are the same, as is clear from our study and those of Biofeedback training or voluntary control." This book is recommended to those who have just begun to study biofeedback therapy.

PHILIP C. ROND, M.D.
Tallahassee, Fla.

Love and Ecstasy, *by Arthur D. Colman, M.D., and Libby Lee Colman, Ph.D. New York, N.Y., Continuum (Seabury Press), 1975, 200 pp., $8.95.*

This attractive little book is an essay about human closeness. Its focus is on the "merger felt by two people who are intimate together." Although the authors occasionally allude to sexual intimacy, this does not appear to be their major concern. Their thesis is that ecstasy is a special state of consciousness "in which the sense of one's 'I,' one's personal boundary, is lost through merger with something or someone else." The main message of the book is to suggest that ecstatic merger can best be experienced in two-person relationships. Psychopathological aspects of merger, as during psychosis, nightmares, or intoxication, are mentioned only in passing.

It is extraordinarily difficult to achieve a satisfying verbal definition of love, not to mention ecstasy. The Colmans—she is an English teacher and he is a psychiatrist—tackle this problem in the first two chapters, which deftly blend concepts from philosophy, neurophysiology, and mysticism.

Their central argument appears in the third chapter, titled "The Dyad in Ecstatic Tradition." Here they debate the risks and rewards of romance, religion, and other aspects of ecstatic feeling; quote Martin Buber and Kahlil Gibran; and raise more questions about love than they can hope to answer.

The fourth chapter presents a hypothesis about the infantile origin of ecstatic consciousness based partly on psychoanalytic theory and partly on the authors' own studies of the psychology of pregnancy. Some highly original and very poignantly expressed ideas about ecstasy in childhood, adolescence, and adult life follow in the next three chapters, and the essay closes with an optimistic redefinition of ecstasy as both a feeling and a quality of interpersonal relationship that is to be sought and treasured.

This book is not a scientific treatise aimed at satisfying readers who want to follow logical sequences toward a conclusion. Rather, one gets the sense of two people who are in love talking about what they know, believe, or want to be true. This creates an undulating style that is absolutely delightful at times but also runs the risk of fluctuating between dogma and obscurity. For example,

> We emerge from childhood into adolescence with the sense of an ecstatic past which, if we dare, can be reopened. We fall in love with visions, taste the bliss of orgasm, plumb the private depths of other minds. We nibble at the past and let portions of it become part of our future as well. Occasionally we find a person in whom everything can be combined, who heals our earliest and deepest wound, whom we can love. And then we can struggle and pray for the ecstasy of discovery to last long enough so that a social fabric can be developed which will allow the potential for ecstasy to continue and for our personal love tradition to develop.

An earnest and almost religious quality sets this book in contrast to the more flamboyant and even frankly pornographic publications about ecstatic experience that are available today. For this and other reasons I would have liked to see the Colmans' book produced in a less expensive paperback edition.

PETER F. OSTWALD, M.D.
San Francisco, Calif.

Transpersonal Psychologies, *edited by Charles T. Tart. New York, N.Y., Harper & Row, 1975, 485 pp., $16.50.*

This volume is one of a series of recent studies that reflect a burgeoning interest in the related problems of modifications of consciousness and meditative approaches to religious experience. The study of states of consciousness has long had its place in the range of psychological studies as a legitimate area of interest and investigation for scientific psychology. This book approaches this study from the point of view of the transpersonal (i.e., spiritual or religious) psychologies. The various authors attempt to articulate the attitudes toward religious experience and meditative techniques of a variety of religious traditions and to relate them to more familiar Western scientific categories. In my opinion the enterprise falls far short of success.

The study of consciousness and altered states of consciousness has been the focus of a number of scientific approaches. Neurophysiologists have studied the patterns of physiological functioning of nervous tissue in relation to states of consciousness and arousal. This approach has extended itself in more specialized studies of patterns of brain activity related to altered states of consciousness during sleep and dreaming. The alterations of cortical and reticular activity involved in states of arousal and attention have also been given considerable attention. Changes in the level and specificity of awareness in conditions in which specific areas of brain tissue have been pathologically affected have been a perduring interest of neurologists since the last century. The influence on the central nervous system of drugs that modify the level and the organization of conscious experience has also been an active and important area of scientific research.

The study of conscious experience and awareness has certainly not been foreign to the interests of psychiatrists and psychoanalysts. The study of consciousness and unconsciousness has been an immediate and pressing concern of psychoanalysts from the earliest days of psychoanalytic involvement. I am reminded that one of the special interests of the late David Rapaport—one of the most prestigious and influential of analytic thinkers—was precisely in the altered states of consciousness. Rapaport put considerable effort into the study of the organization of conscious processes, particularly in terms of their cognitive functioning. One of the central points of his work is an attempt to elaborate a theory of consciousness and conscious activity within the psychoanalytic framework. Rapaport himself undertook the empir-

ical observation of states of consciousness other than the alert waking state, particularly such states as automatic writing, daydreaming, hypnogogic reveries, and dreams. Out of this came his work on cognitive structures, which has enriched not only psychoanalysis but the study of human cognition in general.

From a broader perspective, interest in altered states of consciousness is close to the clinical concerns of every psychiatrist and psychoanalyst. In the work of the analyst the induction of an altered state of consciousness that allows for a perceptible shift in the organization of the patient's thought processes is part of the therapeutic regimen. Forms of regression and their influence on the formation of symptoms and on patient behavior is an area open to the experience of every clinical psychiatrist.

Another important area of consideration of altered states of consciousness relates to the recent attempts to implement and study the effects of meditation on forms of psychopathology and mental disequilibrium. In general, one can say that the outcome of such studies has indicated that there are indeed identifiable therapeutic benefits in meditative practice in terms of an inner calming, the alleviation of anxiety, the diminution of certain forms of defensive organization and response, alleviation of compulsive drug taking, and a number of other beneficial outcomes. However, the serious study of such phenomena and their utility in the overall therapeutic enterprise remains to be established and certainly deserves further attention by the psychiatric community.

Unfortunately, if one looks for information or help in any of these important areas from this book he will certainly be disappointed. The most helpful section is that by Dr. Tart himself, in which he points out the limitations of a restrictive scientific methodology and argues quite persuasively that the enterprise of understanding human consciousness and experience cannot be limited to the constraining scientific paradigms imposed by the Western scientific tradition. The problem here is that he seems to be beating a dead horse because even the behavioral sciences have grown out of the largely positivistic and deterministic phase of their scientific development. There seems to be an implicit assumption in the tenor of Dr. Tart's argument that if one can dispose of such positivistic, scientific canons, just about anything goes. There is no attempt here to grapple with the problem of what does go and how one approaches the problems of validation and theoretical understanding when dealing with transpersonal psychologies.

The rest of the chapters of the book are given over to accounts of the meditative experience within various religious traditions. The chapters vary considerably in quality, amount of information, and bias. The more general difficulty in these accounts is that they tend to present a relatively "theologized" account of their respective psychologies that addresses itself little if at all to the scientific interest and cognitive framework of those of us who are mired in the Western psychological tradition. Thus the explicit aim of the book—to translate the mystical traditions of religious orientations into the language of science—seems to me to be far from adequately achieved.

For an account of how these traditions approach the problem of understanding the meditative phenomena they inculcate, however, these accounts are fairly succinct and reasonably focused.

OFFICIAL ACTIONS

Fall Committee Meetings

Following is a summary of the proceedings of the fall committee meetings of the American Psychiatric Association, which were held in Washington, D.C., in October 1975.

The Council on Medical Education and Career Development

RICHARD I. SHADER, M.D., CHAIRPERSON

THE COUNCIL met in March, May, and October 1975. Two new members of the Council, Drs. Paul Fink and Nancy Roeske, were present at the fall meeting.

The Council and its components actively pursued the development, clarification, and implementation of guidelines for continuing education, now a requirement for maintenance of active membership in the Association. A modification of the American Medical Association's guidelines has seemed a desirable format. This would permit the necessary degree of overlap between APA requirements and those of other bodies (e.g., AMA, state medical societies and relicensure authorities, and district branches). The preliminary draft of the guidelines was reviewed and amended to extend Category I coverage to participation in approved educational programs of the Canadian Psychiatric Association. It was also decided that it was essential to have a procedure for resolving disputes over program approval that might occur between individuals and district branches or district branches and area councils. The Council voted that if such disputes occur they will be settled by the Office of Education of APA, with the advice of the Committee on Continuing Education.

The Council decided that an Office of Education would be essential to the furtherance of the educational goals of APA. A new director having the status of a deputy medical director within APA is being sought.

Considerable discussion was focused on the future of certification in administrative psychiatry by APA; the Council recognizes and affirms the value of such certification. The Council again reaffirmed its understanding that APA is not a certifying organization. Therefore, the Council voted again to have the Board of Trustees assist in efforts to have this certifying function taken over by the American Board of Psychiatry and Neurology. The Council deferred action on the request of the Commission on Certification in Administrative Psychiatry to award honorary certificates until the commission submits criteria for such certificates and an outline of the selection process. The remainder of the commission's report was received with thanks.

The *Commission on History*, David Musto, M.D., chairperson, has withdrawn its request for additional funds for the preparation of a history syllabus by Dr. Daniel Blain. It was decided that commission members will assist in the development of relevant history questions that will be made available to the American Board of Psychiatry and Neurology and to the psychiatric self-assessment examination to incorporate into their examinations as appropriate.

The *Committee on Medical Education*, Larry Silver, M.D., chairperson, requested formation of a task force on medical student mental health services. It is felt that comprehensive medical student mental health services should be provided at each medical school and should include the availability of psychiatric services for students as well as supportive counseling, preventive counseling, and advice to students relating to problems or crises within their family or extended family. The Council voted that a task force be established to explore 1) which medical schools provide such services and to what extent; 2) who provides such services when they are available and whether they are a part of the Dean's Office or of the Department of Psychiatry; 3) who finances the salaries and operational expenses for such services; 4) whether guidelines are established relating to confidentiality and responsibility; and 5) where students go for such services when there are none provided by the medical school. Since these issues also relate to the Council on Mental Health Services, it was further proposed that this task force be a joint effort; the committee and the Council on Mental Health Services would each select and finance two

members for the task force. Liaison with the Task Force on Suicide Prevention (Council on Mental Health Services) was recommended.

The *Committee on Continuing Education*, Robert A. Senescu, M.D., chairperson, reported that it is premature to further specify content areas for Category I credits in the guidelines for continuing education; the council agreed.

The Council reviewed a proposal for a colloquium, entitled "How to Teach About Handling Psychiatric Emergencies," to be held July 22–25, 1976, and endorsed the topic and format. The Council felt strongly, however, that the colloquium should be conducted only if this can be done at no additional expense to APA; the Council supports staff time and travel. The subcommittee requested and received approval from the Program Committee for space and time on the program of the annual meeting to present a forum on continuing education for psychiatrists who teach in family medicine residency programs. There will be a formal presentation followed by small group activities focusing on curriculum planning, use of resources, content, methodology, and evaluation. Participants may choose the small group activity in which they wish to work.

The *Subcommittee on Education of Psychiatrists*, Donald Naftulin, M.D., chairperson, requested approval for a one-day conference to be held at the annual meeting in Miami, Fla., on Sunday, May 9, prior to the beginning of the meeting. The conference will consist of simulations in continuing education accreditation, discussion of program substance, and methods of evaluating educational needs. The afternoon will consist of program substance, subdividing into area meetings in which the district branch continuing education chairperson can develop area continuing education committees and discuss needs, areas, and accreditation processes. The Council endorsed this meeting, but only if there were no additional expense to APA.

The Council did not approve the current version of a position statement on foreign medical graduates prepared by the *Committee on Graduate Education*, Bryce Templeton, M.D., chairperson, and instructed the committee to work with the *Subcommittee on Foreign Medical Graduates*, Tsung-Yi Lin, M.D., chairperson, to improve this document. The Council approved the committee's recommendation that APA give high priority and provide staff support to the development of a research proposal to define the goals and objectives of psychiatric residency training. The concerns about the diagnosis and treatment of alcoholism and drug abuse that were expressed in the recent report of the Speaker-Elect should be included in this review. The Council discussed the importance of neurology training during the four years of psychiatric training. Fiscal difficulties were considered. The Council reaffirmed the Board- and Assembly-endorsed principle of flexibility in the opportunities for training in neurology and in the clinical care of medically ill patients and recommended that APA request that the American Board of Psychiatry and Neurology create a firm policy that will increase the potential for reciprocity in training for psychiatrists and neurologists.

Acting on the recommendation of the Committee on Graduate Education that the report of the *Task Force on Research Training*, Frederic G. Worden, M.D., chairperson, not be published in its present form, the Council charged the committee to review the report in more detail and to make further recommendations to the Council at a later date.

The plans for a meeting in Kansas City, Mo., to be held by the American Board of Psychiatry and Neurology and attended by Drs. Shader, Senescu, and A. Freedman and representatives of ABPN, were discussed. The purpose of this meeting will be to initiate multiorganization discussion of certification and recertification. The Council concluded that a task force on recertification should be established to ensure that a thoughtful, forward looking, and balanced view toward recertification can be developed. In appointing this task force, the Council will select some of its own members, consultants, and members of components who have already been working hard on this matter.

The Council responded to a request from the Board of Trustees to develop a method of selection and procedures for nomination of APA representatives to the ABPN. The Council recommended that APA procedures 1) request that the ABPN develop qualifications for the position of director on the Board; 2) adopt these qualifications as criteria to be followed in selecting APA nominees; 3) have the Medical Director develop a list of potential nominees and then submit to the Board of Trustees a minimum of 10 names of individuals who meet the accepted qualifications; and 5) have the Board of Trustees establish a rank order for the nominees by written ballot. It was also recommended that the steps of this process be published annually in *Psychiatric News* and include adequate information about the size and composition (APA, AMA, ANA) of the Board, aggregate data about the sex and race of the directors of the Board, the role of AMA in the process, Board procedures once nominations are received, information about reappointment and length of service on the Board, and a list of present members of the Board including brief biographical data. The Council feels that such an open process would more closely meet the various professional interests of our membership.

The Council thanked Dr. Paul Fink for sharing copies of three recent papers on psychiatry as a primary care specialty. His reports were helpful in focusing the deliberations of the Council on this vital matter. The issues involved in defining psychiatry's relationship to primary care are many and complex and are defined in part by the contexts in which the discussion occurs and in which the primary care is provided. The Council believes that the definition of primary care, which is not fixed at this time, will evolve to better approximate the nation's health care needs and realities.

In preparing testimony in the Senate for the proposed HR 5545, the Council recommended that APA take the following positions.

1. Psychiatry is a primary care specialty, and psychiatrists meet all six criteria of the Association of American Medical Colleges for the primary care physician.

2. With public education and increased availability and acceptability of psychiatric treatment, the public demand for psychiatric services has risen; therefore, an irreducible minimum of residency slots (probably not less than 10%) should be allocated to psychiatry. The planned reduction in the number of foreign medical graduates will probably result in a serious shortage of psychiatrists (the field of psychiatry has had an unusually high proportion of foreign medical graduates).

3. There will be increased need for the teaching of psychiatry to physicians in training and for continuing education in psychiatry in the other primary care specialties.

The Council approved the ABPN statement that individuals who from now on receive training in British programs that meet the rules of American training facilities will receive full credit so they can become eligible to take Board exams.

The Council reviewed the important role of audio and audiovisual materials in the continuing education of the membership. A major source of such materials is the APA annual meeting and other appropriate meetings and functions. In or-

der for APA to develop mechanisms for editorial control of these materials once the economic and proprietary features of this issue are resolved by the Committee on Public Information (Council on Internal Organization), the Council recommended that the Committee on Continuing Education work in liaison with the Committee on Public Information to initiate the development of appropriate policies.

After reviewing the letter of July 22, 1975, to Dr. Marmor from Elaine Knutsen, M.D., consultant to the Task Force on Suicide Prevention (Council on Mental Health Services), regarding the mental health needs of the members of the psychiatric profession and their families, the Council recommended that any further study generated by the task force be referred for action to the Council on Mental Health Services and that liaison be established on such projects between the Council on Mental Health Services and the Committees on Graduate Education and Continuing Education of this Council.

The Council reviewed the importance of the annual meeting in the continuing education efforts of the Association. It was felt that the priorities of the Program Committee have not always been consistent with those of the components of this Council; it was therefore recommended that Dr. Shader discuss with the chairperson of the Program Committee ways to fulfill the mandates of the components of this Council through efficient use of time at the annual meeting.

The Council plans two luncheon meetings during the APA annual meeting in Miami, Fla.

The Council on Mental Health Services

JAMES C. JOHNSON, M.D., CHAIRPERSON

DURING THE YEAR, several task forces completed their work and were discharged with thanks.

The *Commission on Childhood and Adolescence*, Viola Bernard, M.D., chairperson, concentrated primarily on the formation of a new Council on Children, Adolescents, and Their Families. They have developed a charge for this council as well as suggestions for several task forces. Upon recommendation of the Council and the Assembly, the Board of Trustees approved establishment of the new council, to begin in April 1976.

The commission has also maintained collaborative efforts with relevant APA components. It has been intimately involved with the Commission on Judicial Action in its approach to various suits involving child abuse and children's rights.

The *Committee on Financing of Mental Health Care*, William H. Goldman, M.D., chairperson, circulated a draft of its report to the Assembly, to the Board of Trustees, and to appropriate others in July, with feedback to the committee to come via the Assembly through its district branches, area councils, and the Assembly Task Force on Delivery of Mental Health Services. Dr. Goldman discussed the report with the Assembly at its November meeting. When the committee met November 30 with representatives of the Assembly Task Force on Mental Health Services to review the July 1975 draft report, two main issues on which there were differences were clarified. A compromise on these issues was reached through an agreement to further edit section two, "Principles of Psychiatric Coverage Under National Health Insurance," and section three, "Recommended Benefits," so that they would reflect more closely the Assembly task force's position. A general statement on peer review was added to section three. The revised sections were approved in principle by the Board of Trustees in December and referred to the Assembly Executive Committee for approval in February.

It is envisioned that the final report will be published in two separate parts: a relatively brief brochure including the historical background together with sections two and three, and a separate appendix including the supporting data and references.

The Council reviewed the reports of the June and October meetings of the *Committee on Peer Review*, Donald Langsley, M.D., chairperson; the committee also met in February 1976.

The committee proposed several alternatives concerning the establishment of an Office of Peer Review, seen as high priority by both the Council and the committee. The Assembly endorsed and the Board of Trustees approved implementation of one of these alternatives in which one member of the Peer Review Committee will visit the district branches during the next two years to help develop an effective peer review mechanism in each district branch. The committee has identified the chairpersons of components dealing with peer review or PSRO in all of the district branches, established an informational network by soliciting information about operations at the local level, and circulated the minutes of the national committee and other timely information of interest to these chairpersons.

Additional work has been done on model criteria for inpatient services, and criteria for outpatient services are being developed. The committee has developed a three-tiered system of concurrent review with explanatory narratives. It is considering development of a manual on peer review that would be useful to the district branches.

The committee has had constructive meetings with Blue Cross in California and has been involved in a Blue Cross Federal Employees Benefit-National Institute of Mental Health project headed by Dr. Steven Sharfstein. It is hoped that this project will provide additional data on patterns of utilization and cost of mental health services.

Dr. Langsley chairs a new Select Committee on Psychiat-

ric Services Evaluation (SCOPSE-II), a projected NIMH-Department of Defense study of schizophrenics in six metropolitan areas that will use the peer review concurrent review approach.

The *Committee on Federal Government Health Services,* Stewart Baker, M.D., chairperson, discussed the potential impact of the Privacy Act, which became effective in September 1975. The Federal Aviation Administration leans heavily on the quality of information derived directly from the private medical sector and is concerned that this quality will be adversely affected in the near future by the risk of disclosure of medical information to the patient on demand. FAA feels it has an ethical obligation to quickly alert the private medical sector to this new system of contingencies and that the ultimate impact of this act on FAA operations will be to lessen the quality of medical information obtained. The Council endorsed the committee's recommendation that this matter be referred to the Joint Commission on Government Operations for opinions and procedural recommendations.

There has been a shift in personnel planning by the Army that will double the number of women in uniform while decreasing the size of the Army. This new program includes increased emphasis on pregnancy prevention, rape prevention, improved identification of appropriate job skills for women, improving and modifying the stereotype of women in uniform, and other special considerations. The Council endorsed the recommendation of the committee that this question be referred to the Committee on Women for their review and opinions.

The *Task Force on Private Psychiatric Hospitals*, John H. Houck, M.D., chairperson, has completed its work and submitted a final manuscript and was discharged with thanks. This scholarly and informative report not only elucidates the present status of private psychiatric hospitals in the delivery system but also highlights remaining issues to be investigated. The tentative conclusions were that the private psychiatric hospital accounts for 6% of the total patient care episodes in the United States; this is a fairly consistent figure. The population profile served by the private psychiatric hospital is different in important aspects from that of the population served by the public mental hospital. This reflects the persistence of a two-tiered system of care for mentally ill patients requiring hospital services. These differences in care are unresolved issues. Patterns of delivery of care are shaped by mechanisms of payment for such services, but there is no presently available system of evaluation. Further attention to these unresolved areas will be a continuing concern of this Council.

The Council recommended, and the Board of Trustees approved, publication of the report of this task force along with the reports of the Task Force to Study the Status of Psychiatric Services in Nursing Homes and Other Extended Care Facilities and of a previous Task Force on Public Mental Hospitals.

The *Task Force to Study the Status of Psychiatric Services in Nursing Homes and Other Extended Care Facilities*, Seymour J. Veiner, M.D., chairperson, completed its work and was discharged with thanks. The following recommendations were made by this task force.

1. A component on psychiatric matters relevant to the aged, long-term health care facilities, and residential care facilities should be established. The Council plans to establish a task force to study staffing in various types of facilities.

2. There should be appropriate communication about matters pertinent to the aged and facilities for their care during APA's ongoing liaison with executive and legislative branches of the federal government. This recommendation was referred to the Joint Commission on Government Operations.

3. There should be communication with other interested organizations such as the American Medical Association, the American Nurses' Association, etc., indicating APA's interest in the psychiatric requirements of the aged, particularly in nursing facilities. This recommendation was referred to the Council on Professions and Associations for study by the Committee on Psychiatric Nursing and the Committee on Liaison with the American Hospital Association.

4. The APA Central Office should have a compendium of educational and source material available to interested parties. This was referred to the APA Librarian for comment.

5. District branches should take cognizance of the status of psychiatric services to the aging and to nursing homes in their areas, and legislative committees of district branches should be made aware that geriatric matters must not be neglected in their educational endeavors with legislators at local and state levels. These matters were referred to the Assembly for discussion by legislative representatives and in the district branches.

The *Task Force on Suicide Prevention*, Matthew Ross, M.D., chairperson, completed its charge, submitted a final report, and was discharged with thanks.

Statistical evidence prior to final analysis and refining indicates that the suicide rate among psychiatrists is higher than among other physicians and that the suicide rate among female psychiatrists is particularly high.

The task force had proposed a psychological autopsy study. This proposal, together with appropriate background material, was referred to the Council on Research and Development for its consideration.

The *Task Force on Collaboration of the Psychiatrist and Consumer in Psychiatric Programs*, June J. Christmas, M.D., chairperson, has completed its work and was discharged with thanks. The Council endorsed their recommendation that citizen involvement at the local community level should be through development of citizens' liaison councils and this was referred to the Assembly for implementation. The Council was unwilling to endorse the recommendation that APA develop a National Citizens Advisory Council with broadly representative membership, feeling that a national council was probably not necessary and might well be ineffective compared to one at a local or state level. The full report was circulated to the Reference Committee and there will be further discussion of it at the next meeting of that committee.

Stanley Holzberg, M.D., will chair a new *Task Force on Rehabilitation*, established by the Council at its October meeting. The task force will provide liaison for APA to counterpart elements of organizations, agencies, and institutions that have requested such liaison, as well as appropriate others, and develop a proposal for a structure within APA to act both independently and in conjunction with other organizations to contribute psychiatric input into all types of rehabilitative service.

The Council had been charged with updating the present position statement on "Organizational Structure of State Mental Health Programs." Dr. William Spriegel, after conducting a survey of district branches for the Council and in conjunction with Dr. James Lowry, prepared a revised position statement reflecting the opinions voiced by the district branches. The statement was endorsed by the Assembly and approved by the Board of Trustees in December and was published in the March 1976 issue of the *Journal*.

The Council was also charged with making recommendations relative to the different administrative responsibilities of nonmedical administrators and psychiatrists and attempting to provide a procedure for resolving possible conflicts within institutions where such a pattern exists. The recommendations of the Council were endorsed by the Assembly and approved by the Board of Trustees in December. Implementation will include a revision of Standard 15 of "Standards for Psychiatric Facilities" and establishment of an Assembly task force or survey of district branches to gather documentation or strong presumptive evidence of the incidence and prevalence of such conflicts.

The Council on Research and Development

LOUIS JOLYON WEST, M.D., CHAIRPERSON

DURING THE PAST year, the Council met three times—in April, at the annual meeting, and during the fall committee meetings. In May, Charles Gaitz, M.D., joined the Council, John J. Schwab, M.D., resigned, and Leigh M. Roberts, M.D., replaced E. Ivan Bruce, M.D., as the Assembly liaison. Continuing members of the Council during 1975 were Bernard C. Glueck, M.D., vice-chairperson, Lester Grinspoon, M.D., and Walter W. Shervington, M.D. James H. Carter, M.D., continued as observer/consultant. Nelson Hendler, M.D., was the Falk Fellow assigned to the Council. Other Falk Fellows and APA Fellows attended various meetings as observers.

After the report of the *Task Force on Lithium Therapy*, Irvin M. Cohen, M.D., chairperson, was completed, the task force was dissolved with thanks. In view of the importance and timeliness of the report, the Council recommended early publication; the report was published in the September 1975 issue of the *American Journal of Psychiatry*. The Council also saw a need for periodic reassessment of indications and contraindications for lithium therapy and may propose appointment of a new task force in two or three years to prepare a progress report.

The *Task Force on Methadone Therapy and Narcotic Antagonists*, Roger E. Meyer, M.D., chairperson, presented its final report to the Council. The report consisted of a summary of an earlier, multiauthored review. While informative, it had been largely superseded by several recently published articles. The Council therefore decided that the report should not be published as an official APA document, particularly as the field is still in a state of flux. In view of the fact that federal guidelines on this issue are changing, and because of discrepant views (not yet resolved by data) on this controversial subject, the Council dissolved the task force with thanks.

The *Task Force on Evaluation Research in Community Mental Health Centers*, Gerald L. Klerman, M.D., chairperson, was dissolved with thanks for its work. In 1974 it recommended that the APA Central Office join with NIMH to develop a commission to conduct ongoing evaluations of community mental health centers. Because of changes in NIMH policy, this was not accomplished; thus the task force could go no further with its mandate.

The *Task Force on Psychiatric Aspects of the Aerospace Program*, previously approved but never activated, was reconsidered. The Council noted the uncertainty of the relevance of the task force's charge to the broad APA activities and the insufficiency of available data. The Council decided that this task force should not be activated. It was thought that at some future time the Council should consider the advisability of establishing a new task force on the subject of "Man and Machine—Problems of Adaptation." Such a task force could study the entire area of psychiatric problems encountered in intensive care units, sensory and social isolation, the effects of weightlessness, etc. Aspects of the aerospace program could fit into such a larger study.

The *Task Force on Meditation*, James Morgan, M.D., chairperson, submitted a one-page report as a possible position statement for APA. After a list of references is prepared, this report will be submitted to the Reference Committee for approval of publication. Based on its findings, the task force recommended that well-controlled studies be conducted to evaluate the specific usefulness, indications, contraindications, and dangers of various meditative techniques. Such research should also compare various forms of meditation with one another and with psychotherapeutic and psychopharmacological modalities. The task force was dissolved with thanks and with the note that future developments in this area might require the establishment of a new task force in one or two years to review the state of affairs at that time.

The *Task Force on Effects of Television on Mental Health*, James H. Ryan, M.D., chairperson, completed its report and was dissolved with expressions of thanks for its work. The report (which includes several reviews said to represent more than 3,000 references) will be studied by the Council, and copies will be sent to selected experts for critical comment.

Activation of a Task Force on Research on Psychosurgery has been deferred pending study of Dr. John Donnelly's report on his Task Force on Psychosurgery (Council on Emerging Issues), soon to become available.

Other components of the Council reported progress toward their respective goals. Claudewell S. Thomas, M.D., began work on his Board-authorized study of "Role Con-

flicts of Psychiatrists." Dr. Thomas is collaborating with scientists at the UCLA Survey Research Center to develop the questionnaire and research protocol for the study.

The *Commission on Drug Abuse*, Daniel X. Freedman, M.D., chairperson, in preparation for its scheduled termination in 1976, expressed concern about its dissolution without provision being made for something to take its place. A serious need was seen for a mechanism through which APA can respond rapidly to inquiries on drug abuse from various sources or to internal requirements relevant to formulation of APA policy. Over the past five years the Commission on Drug Abuse has been used primarily by the APA Medical Director when urgent information and/or position statements were required in reaction to various critical issues arising in government agencies (including Congress) regarding the use of drugs of all types, especially those subject to abuse. The commission feels that several important responsibilities remain, e.g., keeping the membership fully informed about substance abuse and providing information and advice to various health-related and other agencies, both governmental and nongovernmental, that are (or should be) concerned about the drug abuse problem.

The commission sees five major areas of concern that need to be covered after the present commission is dissolved: 1) government liaison regarding scheduling of drugs, laws regulating treatment, and professional standards (e.g., training and/or use of paraprofessionals); 2) constant monitoring of changing policy issues on the use of drugs, including indications and contraindications for commonly used drugs in psychiatric practice; 3) keeping abreast of and being prepared to deal with potential problems in the future (e.g., the introduction of new substances that may find their way to the street and be abused, proposed new regulations for existing compounds; 4) changing patterns of alcohol and polydrug abuse (especially among teenagers) and how to deal with them; and 5) evaluation of both "standard" and "novel" therapies for drug abuse (e.g., methadone and narcotic blocking agents, drug-free therapeutic communities, meditation).

Based on these needs, the Council recommended to the Board of Trustees that a new Commission on Substance Abuse be established, to report directly to the Board, following the model of the Judicial and Legislative Commissions. Such a commission could itself develop suggestions for specific task force activities that might fall within the province of any of the several councils. A proposal could then be made to an appropriate council suggesting creation of a specific task force.

A progress report was received from the *Task Force on Biofeedback*, Martin T. Orne, M.D., chairperson, Bernard C. Glueck, M.D., Council liaison. This task force is focusing on the clinical significance of work on biofeedback as it relates to psychiatry. It is also defining the limitations of present knowledge about biofeedback. The task force feels that further research is needed before it can report comprehensively on the appropriate uses of biofeedback in psychiatry and in other areas of medicine as well. Areas of special interest are 1) the behavioral significance of biofeedback, 2) cortical and subcortical CNS representations of biofeedback, 3) relevance of biofeedback procedures to psychiatric illness, and 4) relevance of biofeedback procedures to medical problems not specifically psychiatric (e.g., epilepsy and hypertension). The aim of the task force's report will be to clarify the appropriate therapeutic uses of biofeedback at the present time, to delineate those areas which require more detailed research before justifying routine clinical applications, and to identify those areas where clinical application seems unjustified or contraindicated in light of available evidence.

This year the *Task Force on Ethics in Research*, Samuel B. Guze, M.D., chairperson, L.J. West, M.D., Council liaison, Robert J. Ursano, M.D., Falk Fellow, published a letter in the *American Journal of Psychiatry* requesting research protocols to study as precedents for the development of guidelines for ethics in research; response was negligible. As a result, the Council developed a new charge for consideration by the task force. This charge includes 1) review and analysis of ethical guidelines for psychiatric research formulated by other organizations and agencies, 2) delineation of ethical principles appropriate to psychiatric research design, with emphasis on such matters as informed consent and confidentiality, and 3) the provision of a set of sound ethical guidelines for psychiatric research that protect the rights of human subjects and at the same time allow the development of new knowledge.

The *Task Force on Racism in Psychiatric Research*, Claudewell S. Thomas, M.D., chairperson, Walter W. Shervington, M.D., Council liaison, is developing a questionnaire to be sent to various institutions doing research, asking them to identify the names of researchers who themselves represent minority groups. A second questionnaire will then be sent to the researchers so identified in order to gather information about various aspects of their research within the general context of how racism in all of its forms might be affecting their research activities, including problems of obtaining support. The results of these questionnaires will form the basis of a report to be produced by the task force. During this year the task force submitted a grant proposal to the Center for Minority Studies at NIMH to support this study but subsequently decided to withdraw the application.

Because of the large scope of its work, the *Task Force on Nomenclature and Statistics*, Robert L. Spitzer, M.D., chairperson, Bernard C. Glueck, M.D., Council liaison, Conrado Weller, M.D., Falk Fellow, has eight members, four official consultants, and over 30 special consultants. The task force has produced several documents to date: 1) a critique of *DSM-II* (with changes proposed for *DSM-III*); 2) an initial draft of *DSM-III* classifications, and 3) first drafts of texts for the sections on schizophrenic disorders, mood disorders, anxiety disorders, hysterical disorders, personality disorders, disorders arising in childhood, disorders of basic biological functions, stress disorders, impulse disorders, and miscellaneous matters. Still to be drafted are sections on organic mental disorders, alcohol and drug dependence, and paranoid disorders.

On June 10–12, 1976, the APA and the University of Missouri will cosponsor a conference on "Improvements in Psychiatric Classification and Terminology: A Working Conference to Critically Examine *DSM-III* in Midstream." This conference will provide a unique opportunity for invited experts in the areas to be covered in *DSM-III* to discuss and critique the task force's work to date. The information derived from the conference will also be used to develop an improved *DSM-IV*.

The Reference Committee, and subsequently the Board of Trustees, approved a recommendation by the Council that this task force be given every encouragement and support to produce *DSM-III* as speedily as is consistent with comprehensiveness and excellence. Accordingly, funds have been shifted within the Council's budget to provide additional support for this task force in the present year, and $25,000 has been approved for its work next year.

Four new task forces were approved by the Council this year.

1. The *Task Force on Electroconvulsive Therapy*, Fred Frankel, M.D., chairperson, Lester Grinspoon, M.D., Council liaison, quickly became embroiled in the national controversy surrounding ECT. At its first meeting, the task force concluded that the present crisis over ECT, including legislative actions being considered by several states, represents a major crisis for all of medicine. The response of the American Psychiatric Association to this particular issue of legislative control over medical practice will be very important and may provide a model for future activity.

The task force decided that its final report should include statements on the clinical efficacy of ECT, unestablished or experimental uses, adverse effects, methods of administration, basic science, social, moral, and legislative issues, training and education, and areas for further study. These statements should be based on all currently available empirical evidence (gleaned from a search of the literature, open hearings, a questionnaire study of the APA membership, and data collected about ECT use at high-caliber U.S. institutions).

While gathering and formulating this information will be expensive, the Council strongly supported the prospect of its speedy accomplishment. The council felt that this is an issue vital to all members of the APA, whether or not they use ECT in their practice. Because it is of such unusual importance, immediate funding is essential in order to develop the necessary information and successfully represent the Association and the various district branches in present and prospective legal and legislative issues surrounding ECT. Therefore, the Council urgently recommended that APA either help obtain the needed funds from other sources or provide the funds itself without delay.

2. The *Task Force on Research on Aging*, Carl Eisdorfer, M.D., Ph.D., and Lissy F. Jarvik, Ph.D., M.D., cochairpersons, Charles M. Gaitz, M.D., Council liaison, was given a charge by the Council chairperson. The task force has two years in which to address some fundamental issues in research, education, and treatment of the elderly. Members of the task force are Robert Butler, M.D., Eric Pfeiffer, M.D., and Alexander Simon, M.D.

3. Establishment of the *Task Force on Ethical Considerations in Behavioral Therapy*, Lee Birk, M.D., chairperson, Lester Grinspoon, M.D., Council liaison, was approved by the Council in April but tabled in October. The American Psychological Association currently has a multidisciplinary commission working on this subject. The Council wants to review the report of that group before proceeding with work by its own task force.

4. A *Task Force on Poverty and Requirements for Psychiatric Resources* was approved for establishment under the Council's auspices in response to the report of the Task Force on Delivery of Psychiatric Services in Poverty Areas (Council on National Affairs). The issues raised by the report were services for children and adolescents, services for the elderly, professional roles and skills, and professional rewards.

Before work began on this task force and after further consideration of these four issues, the Council concluded that a more efficient way to deal with three of them was to establish a new Task Force on the Role of the Psychiatrist in Poverty Areas under the Council on Mental Health Services, and the Council recommended this to the Board. The remaining issue, services for the elderly, will be referred to the new Task Force on Research on Aging.

Other Council actions during the year included 1) a request for establishment of a Task Force on the Aging Psychiatrist, which was referred to the Council on Internal Organization, 2) a decision not to establish at this time either a Task Force on Children and Religious Cults or a Task Force on Acupuncture, and 3) a recommendation that the Association (under the Division of Membership Services and Studies) sponsor the analysis of data already gathered on psychiatric manpower issues rather than initiating a new task force on manpower at this time.

The Council on National Affairs

HAROLD M. VISOTSKY, M.D., CHAIRPERSON

REVIEWING ITS CHARGE, role, and functions the Council affirmed or reaffirmed 1) the responsibility of monitoring the quality and output of the components of the Council and taking a strong organizational role in making direct input, 2) a commitment to activity, and 3) a responsibility to direct components to determine areas of common concerns. In considering several requests for reconstituting task forces as committees, the Council determined that there is a need to develop a policy regarding the development or evolution of permanent organizational components to assure representation of the underrepresented groups. The Council agreed that there should be a developmental period (the task force period) during which the minority professional membership is identified and organized into a coherent entity to make policy statements relative to common interests of the ethnic professionals represented by the committee charge. In accord with this proposed policy, the Council approved recommendations from the Task Force on Indian Affairs and the Task Force on the Mental Health of Spanish-Speaking People in the United States for restructuring as committees. These recommendations were approved by the Reference Committee and the Board of Trustees. Each component of the Council was urged to carefully consider the report of the Task Force on Mental Health Services to Poverty Areas and to forward its recommendation to the Council. Dr. Visotsky requested recommendations to the Task Force to Study Arbitrary Discrimination Against Persons with Previous Psychiatric Treatment.

The Council received the final report of the *Task Force on Third Party Intervention in Community Crisis*. Burr Eichelman, M.D., who had assumed responsibility for evaluating questionnaires circulated to a random sample of the membership, reported that 50% of the respondents have encountered community crisis (more than 25% have been actively involved in conflict resolution), and only 10% of the respondents were trained for these experiences (more than 50% indicated willingness to be trained).

The Council recommended that 1) Dr. Eichelman report the study in an article to be submitted to the *Journal* for publication, 2) a copy of the paper be directed to the Council on Medical Education for use in resident training and continuing education seminars, and 3) through an announcement in *Psychiatric News* and to district branches, a roster of interested members be developed.

During the year Johanna Clevenger, M.D., succeeded Morton Beiser, M.D., as chairperson of the *Task Force on Indian Affairs*. A unique feature of the task force has been its liaison activities with American Indian groups and projects. These include the Association of American-Indian Physicians, a component of the American Academy of Child Psychiatry, the Association of American Indian Affairs, the Association of Native American Medical Students, the Indian Health Service, and the American Indian and Alaskan Native Mental Health Research and Development Center. The task force was successful in obtaining funds from the Ittleson Family Foundation for a conference on the mental health of Indian youth. The conference, held in Portland, Ore., in April 1975, attracted a large number of Indian and non-Indian participants and was regarded as a very successful meeting. A monograph of the proceedings is being developed. Another major undertaking was the preparation of a summary of the evaluation of available programs and resources for American Indians; this report was developed under a contract with the Indian Health Service.

Several activities of the *Task Force on the Mental Health of Spanish-Speaking People in the United States*. Angel G. Gomez, M.D., chairperson, have served as a unifying and cohesive force for Spanish-speaking psychiatrists. In particular, a newsletter was published that included information on the activities of the task force and other matters of interest to Spanish-speaking psychiatrists. Efforts have been directed toward appointing additional Spanish-speaking psychiatrists to the various organizational components of the Association and planning the Simon Bolivar Lecture for the annual meeting.

The *Committee of Black Psychiatrists*, Charles B. Wilkinson, M.D., chairperson, has maintained active liaison with the Solomon Carter Fuller Institute and the Center for Minority Group Mental Health Programs. In keeping with the theme of the 1976 annual meeting, the committee selected a historian, Dr. John Hope Franklin, to receive the Solomon Carter Fuller Award and invited him to deliver the Fuller lecture. The task force communicated with the Task Force on Nomenclature and Statistics about the inclusion of racism in the diagnostic nomenclature and with the Assembly's Task Force on Key Conference Recommendations regarding procedures for assuring adequate representation of racial minority-group members. In response to President-Elect Gibson's inquiries, the committee recommended that all minority group members be considered in appointments as observer-consultants.

A number of position papers were solicited and received for discussion at the initial meeting of the new *Task Force of Asian-American Psychiatrists*, Lindbergh S. Sata, M.D., chairperson. These papers were solicited from a broad cross-section of the membership, focused on topics related to Asian-Americans and Asian refugees and mental health issues, and enhanced the productivity of the meeting. The task force has initiated a survey of identifiable Asian psychiatric resources. The need to document Asian mental health delivery system models for interested Asian psychiatrists was recognized as a potential function for the task force. Other areas of study included 1) the geographical distribution of Asian psychiatrists as related to the restrictive regulations for licensure, 2) the special requirements of continuing education for racially diverse multilingual Asian psychiatrists, and 3) the resettlement of Vietnamese refugees, which was partially resolved in the recent formation of an advisory council, composed entirely of Vietnamese and Cambodians, that assures relevant representation and input for all future refugee activities. In addition, individual task force members have been in contact with a variety of Asian community agencies that are actively developing supportive and rehabilitative services for the refugees. The recognition of the lack of Vietnamese psychiatric resources within APA and the awareness that a variety of projects have already been initiated by Asian com-

munity agencies led to the recommendation that the Association be available but unintrusive. The task force will attempt to communicate with relevant Asian groups to avoid the misconstruing of our actions by sensitive community groups. It was further agreed that two key roles of the task force would be active support of community efforts to provide humanistic services to the refugees and serving as a conduit for pertinent information received regularly by the APA Central Office to the task force members. It was further suggested that, while actual statistics are not currently available to the task force, approximately two-thirds of the refugee population is of middle-class origin, and for those conversant in French, French-speaking psychiatrists could be used if psychiatric intervention is indicated.

Before the formal opening of the fall committee meetings, the *Committee on Women* held a dinner meeting that was attended by the majority of women members of the various components in addition to two guests from the American Psychological Association. Several reports dealt with liaison activities with other components and the overall increase in activities and contributions of the women members of APA. Other activities reported during the proceedings of the committee meeting were Dr. Virginia Davidson's development of a handbook for assistance in the organization of committees on women in the district branches, and the development of a bibliography on the needs of residents. Drs. Nancy Roeske, Elaine Hilberman, and Anne Seiden reported on their respective research projects. The Council approved the recommendation submitted by chairperson Elissa P. Benedek, M.D., that APA publish Dr. Hilberman's monograph on rape. This recommendation was approved by the Reference Committee and the Board of Trustees.

Aristide H. Esser, M.D., has served as the acting chairperson of the *Task Force on Ecopsychiatric Data Base*. Liaison was established with the Committee on Comprehensive Health Planning to develop position statements—one related to the quality of life and the other related to health planning. Both statements were approved by the Council and referred to the Reference Committee, which took no action on the latter statement because the language was incorporated in the report of the Committee on Comprehensive Health Planning. The position statement on the quality of life was approved, pending editorial changes, by the Reference Committee. Other areas of study of the task force included alternative environments for troubled youth and environmental issues related to unemployment.

The *Committee on Comprehensive Health Planning*, Robert L. Williams, M.D., chairperson, was reconstituted from a task force. Additional responsibilities and activities have stemmed from the passage of the National Health Planning and Resources Development Act. To assist in the work of the committee, the Board of Trustees approved the creation of a staff position. Mr. Sam Muszynski was appointed to this position and has worked closely with the committee in following the planning of the proposed program. A comprehensive position statement developed by the committee was approved by the Council and subsequently by the Reference Committee and the Board of Trustees.

The Council on International Affairs

NORMAN ROSENZWEIG, M.D., CHAIRPERSON

THE COUNCIL CARRIED out several highly successful projects during this past year, including hosting activities at the 1975 annual meeting in Anaheim, Calif., and participation in the first Pacific Congress of Psychiatry in Melbourne, Australia, May 11–16, 1975. The task force that planned the APA participation at the congress was chaired by Dr. Alfred Auerback, and Dr. Floyd Cornelison provided leadership for the preparation of the APA portion of the program. A delegation of Swedish psychiatrists who attended the Anaheim meeting were beneficiaries of a special program planned by a task force under the leadership of Dr. Robert Garber.

Special arrangements for foreign guests at the 1976 annual meeting in Miami, Fla., are being made with the assistance of the Local Arrangements Committee. Immediately after the annual meeting on May 15–18, 1976, a Joint Meeting with the Caribbean Psychiatric Association and the Section on Psychiatry, Neurology, and Neurosurgery of the Puerto Rican Medical Association is being held in San Juan, Puerto Rico. Victor Bernal y del Rio, M.D., is chairperson of the Program Committee, and Jose Fumero, M.D., is supervising local arrangements.

The VI World Congress of Psychiatry will meet in Honolulu, Hawaii, August 28 to September 3, 1977. Shervert Frazier, M.D., is chairing the Organizing Committee and Gerald Sarwer-Foner, M.D., the Program Committee. An office for this congress has been established at APA headquarters, with Ms. Rosa Torres serving as coordinator.

The Board of Trustees approved APA cosponsorship of the Congress of the World Federation of Mental Health in Vancouver, B.C., Canada, in August 1977.

The *Task Force on Liaison with International and Foreign Psychiatric Organizations*, Nathan S. Kline, M.D., chairperson, is developing a roster of resource people who have extensive knowledge of a country or region. The Association could consult with these people on short notice when problems or questions arise concerning a particular area.

The *Task Force on Transcultural Aspects of Ethnocentricity Among Psychiatrists*, Ramon Parres, M.D., chairperson, continues to refine the questionnaire being used in their interviews designed to measure ethnocentricity. Preliminary interviews have been done in Canada, Mexico, New Jersey, and Louisiana.

The *Task Force on Psychiatry and Foreign Affairs: Psychological Aspects of Near Eastern Studies*, William D. Davidson, M.D., chairperson, held its final meeting in October 1975. During the past two years, the task force participated in meetings at Princeton University, the University of London, Georgetown University, and the U.S. State Department. Its insights and approaches to some of the problems in the Middle East were valuable contributions.

Two new task forces are being initiated this year. The *Task Force on Cross-Cultural Perspectives of Psychiatric Practice*, Joseph T. English, M.D., chairperson, held its first meeting in Washington, D.C., on Jan. 23, 1976. Rita Rogers, M.D., will chair a new *Task Force on Psychiatry and Foreign Affairs; the Cyprus Conflict.*

The *Inter-American Council of Psychiatric Associations* held a business meeting in Mexico City on January 26 and 27, 1976. The first printing of the Spanish edition of the *Psychiatric Glossary*, royalties to the IACPA, will be distributed only in Mexico until a suitable translation can be done for the other countries in Latin America.

The Council on Professions and Associations

RUTH I. BARNARD, M.D., CHAIRPERSON

THE NEW MEMBERS of the Council are Leon Roth, M.D., and Warren Williams, M.D. The latter was appointed to complete the term of Lewis L. Robbins, M.D., who was elected trustee-at-large.

The *Committee on Liaison with American College of Physicians*, Charles P. Neumann, M.D., chairperson, is concentrating on reviewing its past role and functions, determining its goals, and identifying more precisely the current problems of joint concern to APA and ACP. Dr. Neumann has completed his term of office, having served as an active member for six years and as a most productive chairperson for the past three years.

The *Task Force on Confidentiality as It Relates to Third Parties*, Maurice Grossman, M.D., chairperson, has completed its work and its report has been published. A new Committee on Confidentiality will be established within the Council on National Affairs in May 1976. This new component will provide a continuing mechanism to discover, disseminate information about, and coordinate efforts to deal with problems of confidentiality on a national basis.

The Council continues to monitor the Insurance Coding Project developed by this task force. Dr. Grossman and Dr. Richard Johnson are pursuing this issue with representatives of the Health Insurance Council (HIC) in an effort to find a way to provide insurance companies with the information they need to process patients' claims for psychiatric treatment while preserving an adequate degree of confidentiality. A coding system has been worked out and is ready for a field trial with a substantial number of insurance companies that are members of HIC. There has been difficulty, however, in getting support and participation in this trial from a sufficient number of district branches. The project is neither complicated nor expensive, and it is very important that whatever problems the district branches are having in understanding and cooperating in the field trial be solved before we lose the excellent cooperation we have had with HIC.

The *Committee on Psychiatry and the Law*, G.J. Sarwer-Foner, M.D., chairperson, undertook the development of a model commitment law, as charged by the Reference Committee and the Council. When consensus has been reached, the recommendations of the committee will be put in proper legal language by attorneys. This work is progressing actively and is the main current thrust of the committee. Freedom, involuntary hospitalization, the ethics of psychiatry, the right to individual freedom and liberty, the right to be protected and treated, as well as the right to refuse treatment are among the concerns and issues the committee is dealing with. Dr. Stanley Portnow is the committee's representative for further testimony (if necessary) before the Senate regarding APA's stand favoring retention of insanity as a defense as it relates to proposed Senate Bill 1 and Senate Bill 1400.

The committee expressed thanks for the contributions of Professor Henry H. Foster, Jr., and Ephraim Gomberg from the Family Law Section and the Section on Criminal Law of the American Bar Association and asked them to continue in the work of the committee.

The *Task Force on the Right to Treatment*, Jonas R. Rappeport, M.D., chairperson, was to have completed its work this year; its position statement was accepted by the Reference Committee and the Executive Committee of the Board of Trustees in June. However, the Assembly did not accept the statement in its entirety, and the task force will therefore be continued until a position statement acceptable to all can be formulated.

The report of the *Task Force on Religion and Psychiatry*, Abraham N. Franzblau, M.D., chairperson, "Psychiatric Services to Religious Institutions and Viewpoints on Religion," is in press. The final phase of its work will be completed by October 1976.

The *Committee on Liaison with American Hospital Association*, Francis de Marneffe, M.D., chairperson, reported that there has been continuing active exchange of information between APA and AHA regarding pending legislation, federal regulations, national health insurance, and confidentiality of records.

The committee asked for support of House Rule 3658 and Senate Bill 1678 as well as House Rule 8231 and Senate Bill 2258. If passed, they would require that regulations be reviewed by Congress to ensure that they actually conform with the intent of Congress.

On mutual agreement with the AHA and for reasons of economy, the number of members will be reduced from six to four persons on both the APA committee and its AHA counterpart.

The *Committee on Psychiatric Nursing*, William B. Stone, M.D., chairperson, in collaboration with their American Nurses' Association counterpart, participated in APA's 1975 Institute on Hospital & Community Psychiatry. A session on "Predicting Interprofessional Alliances in the 80's" was held.

The committee has completed a first draft on the nurse psychotherapist, which is now being studied by the American Nurses' Association. It is hoped that this statement will be approved by both ANA and APA.

The committee has been performing a very important but informal liaison activity with ANA, particularly through its chairperson, and recommends that this be formalized by the APA President appointing an individual member (who is not the chair of the committee) as APA's representative to ANA. The Council referred this recommendation to the Task Force on Liaison Activities for inclusion in their overall conclusions.

The *Task Force on Liaison Activities*, Walter E. Barton, M.D., chairperson, in its first report identified and categorized liaison activities as either extra-APA, both substantive and ceremonial, or intra-APA, between councils and components with interface with staff at all levels. The task force is mainly concerned with developing guidelines for liaison activities, criteria for their establishment, and mechanisms for accountability.

The *Task Force to Study Standards and Guidelines for Psychiatrists Working with Paraprofessionals*, Donald H. Naftulin, M.D., chairperson, is composed of three persons in geographical proximity who will formulate standards and guidelines for psychiatrists working with paraprofessional personnel as supervisors, consultants, trainers, administrators, etc. Their report is expected by October 1976.

The Council on Internal Organization

MILTON GREENBLATT, M.D., CHAIRPERSON

THE COUNCIL MET in mid-October 1975 and heard from its many components. The actions that took place at that meeting and further actions by the Reference Committee and Board of Trustees at subsequent meetings will be described in this report.

The Council, together with business consultants, reviewed the work of the advertising agencies that handle APA's account for the *American Journal of Psychiatry*, *Psychiatric News*, *Hospital & Community Psychiatry*, and APA's exhibit programs. The agency for the *Journal* and *Psychiatric News* reported that revenues were satisfactory, with a general increase since the major dip around the time of the Hawaii meeting. The circulation of *Hospital & Community Psychiatry* has grown to about 17,000. One consultant stressed the importance of ethical standards in advertising and indicated that advertisers could probably be held easily to the ethical standards prescribed by APA. Another consultant remarked that APA's journals are holding their own despite increased competition and the fact that relatively few drugs are prescribed by psychiatrists. The commission that APA pays its advertising agencies may be slightly higher than the prevailing rate in general industry. Therefore, the Deputy Director for Business Administration was authorized by the Council to renegotiate contracts to achieve a saving.

Dr. Henry Laughlin chaired a study, undertaken with the aid of APA staff, of the history and purpose, costs and revenues, and current operations of the Hospital & Community Psychiatry Service and journal. Dr. Laughlin concluded that these interdependent operations merited high marks for both services rendered and cost efficiency. The APA contribution to these functions has increased in recent years for three main reasons: 1) a full overhead charge is now being made (for tax purposes), 2) subscription fees had not been raised commensurate with increasing costs, and 3) advertising revenues dipped last year. Fees have now been raised for the coming year, and vigorous circulation promotion efforts will be made. Advertising revenue shows signs of improvement, and rates will be raised.

The Council approved of the measures being taken to increase revenue and will continue to monitor these operations for the purpose of stimulating progress toward greater self-sufficiency and continuing program improvement. The Board of Trustees also requested that the Council review these operations again in one year.

The *Institute on Hospital & Community Psychiatry Program Committee*, Alyce C. Gullattee, M.D., chairperson, reported that the contributions at the recent institute were of a high quality and that the institute is regarded as a major continuing education effort, especially for ancillary personnel; Dr. Henry Work reported that 916 persons attended and that one-third of them received the Hospital & Community Psychiatry Service.

The Council recommended that the service be kept under continued monitoring and that further thought be given to possible modification of journal policy, leading to higher quality articles that might command a larger audience without sacrificing their appeal to the wide sectors of ancillary and allied personnel.

The *Task Force on Interface Between Industry and Psychiatry*, Harvey J. Tompkins, M.D., chairperson, recommended (and the Council, Reference Committee, and Board of Trustees later approved) that a Committee on Advertising Policy reporting to the Council be established. This committee would review advertising policy, monitor ads, resolve or finally adjudicate any differences that might occur among the editors of various APA journals, and be the final arbiter regarding the acceptance of ads that the editors believe may violate our advertising guidelines. The task force also reviewed and approved "Principles and Guidelines of Advertising Acceptance."

The Council discussed the ethical issues raised in the task force report and recommended, with subsequent concurrence by the Reference Committee and Board of Trustees, formation of a Task Force to Study the Impact of Potential Loss of Pharmaceutical Support. Such loss might result if pharmaceutical advertising and other direct and indirect support of APA by drug firms were terminated. Task force members, some of whom will be drawn from the Assembly, will also consider the related ethical issues that exist whenever APA receives funds from pharmaceutical companies for any purpose.

The Task Force to Study the Impact of Potential Loss of Pharmaceutical Support was granted $3,000 funding for fiscal year 1976–1977.

Peter A. Martin, M.D., chairperson of the *Committee on Program*, noted that the committee has been moving gradually from a "receptive" position to a more "active" position in stimulating submission of special sessions at the annual meeting to cover areas deemed important to a well-balanced program of continuing education. He stressed the importance of setting a central theme for the meeting very early in the year in conjunction with the President. The committee recommended the continuation of the open policy on panels as an excellent safeguard for participation in the program by the entire membership.

Twenty courses with an enrollment fee of $15 will be offered at the 1976 annual meeting; this continuing education program will be self-sustaining. Teaching tapes will run continuously through the day at the meeting and will provide AMA Category I credit for participants. There will also be a program of current films of interest to the membership.

There are numerous issues connected with recording, editing, and selling tapes of presentations at APA's various meetings. A task force may be established to consider these factors, but in the interim Mr. Robert L. Robinson, Director of Public Affairs, has been authorized by this Council to explore development of teaching tapes from the 1976 annual meeting and to report his findings to an early meeting of the Reference Committee.

The *Committee on Conventions*, W. Edward McGough, M.D., chairperson, recommended, with endorsement or approval by the Council. Reference Committee, and Board, that 1) a brief description of the placement service program be published in *Psychiatric News*, that employers and applicants who wish to use the service be encouraged to apply through the Membership Services Department, and that completed forms be reproduced and made available at the Placement Service booth during the annual meeting; 2) the Task Force on Arrangements assume responsibility for ensuring that adequate facilities be available for day-care services for children at the annual meeting, such program to be self-sustaining through charges to cover expenses; 3) the Board of Trustees endorse appointment of an ad hoc committee on spouses' scientific program; 4) certain categories of registration fees be increased to help defray the escalating costs of the annual meeting; 5) the Subcommittees on Technical and Scientific Exhibits be merged; and 6) exhibitors of sex therapy and related films rent an exhibit booth for placement of orders, exchange of technical data, etc., but that films be viewed in a separate sound-controlled room, with viewing limited to professionals.

The *Committee on Public Information*, Eric Plaut, M.D., chairperson, recommended hiring an assistant to the Director of Public Affairs, and the Board of Trustees approved implementation by the Medical Director, within available funds for program expansion. The committee also recommended a survey of district branches to identify their public information components and activities and a number of long-range plans, including development of a Joint Commission on Public Affairs, holding a conference relating APA to the media, creation of a Media Advisory Board, and a new popular publication to help build a better image for psychiatry.

The Board disapproved the committee's recommendation that a Commission on Public Affairs be formed to report to the Board.

The *Committee on Member Insurance and Retirement Plans*, Chester L. Trent, M.D., chairperson, brought several matters before the Council.

1. Professional Liability Insurance Program. The Council, the Reference Committee, and the Board approved a change in rates for professional liability insurance and recommended that filing of rate schedules for the states of California, Florida, New York, and Ohio be delayed until after Jan. 1, 1976, and that a study be undertaken of actuarial problems where serious rate differences exist between different companies in the same state.

2. Retirement Plan Trust. Results of a reevaluation of the APA member retirement plan, together with concerns relative to a recent audit of the plan, point to the need to make new arrangements for offering a retirement plan to APA members. The Retirement Plan Trustees recommended that the Retirement Plan Trust be dissolved and appropriate functions of the trust be transferred to a corporate trustee or other appropriate investment custodian. The Council, the Reference Committee, and the Board approved this recommendation with the understanding that the Retirement Plan Trustees will present a detailed proposal for final approval at a later date. These actions will in no way jeopardize existing member pension benefits.

The Board also approved funding a one-year task force study to consider problems (and their possible solutions) faced by persons with a psychiatric history in obtaining insurance.

Joan Eccleston, M.D., chairperson of the *Committee of Residents*, reported that the committee has markedly increased its liaison activities during the past year, both within and outside APA and its district branches. The committee has developed a recruitment packet for residents and has planned a series of editorials on issues of interest to residents for publication in *Psychiatric News*.

Upon recommendation of the committee and the Council, the Reference Committee will refer to the Assembly the request that its Membership Committee consider the appointment of an "ombudsor" for resolving disputes between psychiatric residents and residency programs, and will ask the American Association of Directors of Psychiatric Residency Training Programs to review this proposal and provide suggestions for its development and implementation.

The Council and Reference Committee recommended that the Committee of Residents be commended for its extensive activities of the past year on public information, liaison activities, recruitment, problem solving, and ongoing program review; this was endorsed by the Board.

The Council and Reference Committee voted to recommend the following:

1. APA determine and inform the Committee on Women what information exists in its files concerning the participation of women and other minority members at the local and national level as compared with male participation; this would include the number of such members, identification of their representation on district branch and national components, information on full- and part-time practices, and the age when they became active members (approved by the Board).

2. Mechanisms to acquire this information should be established when it is not currently available; such mechanisms would include requesting the Assembly, through its district branches, to provide data about its members (approved by the Board).

3. The President of APA was requested to provide information as to how he handled his appointments to include women and minority members and to make suggestions for the future.

The *Task Force on Manpower Problems*, Richard Steinhilber, M.D., chairperson, worked with Dr. Lee Gurel of the APA Central Office to define two manpower studies that were subsequently approved by the Board for funding by outside sources. The first study would identify nonmember psychiatrists and would assist in more accurately planning for meeting the nation's needs, e.g., in national health insurance, and make possible a complete census of all psychiatrists.

The goal of the second study would be to complete information on nonmembers and to add to existing information on members in a number of critical areas not previously collected, such as primary work site, work status, work activities, type of practice, areas of perceived educational need, and interests in continuing education. All data would be stored in the computer and be available for retrieval. These data would provide a basis for new member recruitment and make possible publication of a biographical directory.

Based on recommendations of the Committee of Residents, Drs. Gurel and White of the APA staff, the Council on Internal Organization, and the Reference Committee, the Board of Trustees requested that staff explore revision of the APA's membership brochure, as suggested at the Key Conference. Development of the brochure would be undertaken by the Committees on Membership of APA and the Assembly and by the Committee of Residents. Although this is considered a high priority, funds are not currently available to complete the project.

The Board accepted with thanks a review of APA campaign procedures for national elective office and for the mailing of related political literature. The Council designed guidelines in both areas to ensure the highest level of ethical political conduct among those seeking office in APA.

A further analysis of APA's councils and committees was made by Dr. Jack White and Ms. Patricia Scheidemandel of the Central Office. Some highlights from their study of 63 components include:

1. Men are slightly overrepresented as compared with women in service in APA components.
2. Component members are about five to eight years older on the average than APA members; however, some of the younger members, such as Falk Fellows, were not included in the analysis.
3. A comparison of the geographic distribution of component members with the general distribution for APA members showed that Massachusetts had about twice as many component members as the general APA population, and New York had fewer than might be expected. When viewed by census divisions, New England had about twice as many component members as might be expected, the Mid-Atlantic area had fewer, the South Atlantic area slightly more, and the East-North Central area fewer than might be expected. There is little evidence of overlap in objectives among the numerous components.

The Reference Committee endorsed the following guidelines for distribution to all councils and chairpersons of components:

1. Components should participate in the development of the council budget.
2. Financial statements should be made available to components at intervals.
3. Each component would assign specific agenda items to component members, including a budget item.
4. Any unusual or extra expenses of a component would require approval of the chair of the council.
5. Conference calls should be used more often.
6. Some components could function effectively with fewer members.
7. Components could often work as well using members from regional locations rather than having representation from all over the country.

The *Committee on Grants and Awards*, Jack Weinberg, M.D., chairperson, reviewed APA's award program, giving particular attention to two that are running out of funds—the Hofheimer Prize Board and the Vestermark Prize Board.

The Board approved the following recommendations: 1) it become APA policy that all new awards established by APA be self-sustaining, 2) the Medical Director be authorized to seek additional funds to continue the Hofheimer Prize, and 3) the Deputy Director for Business Administration be authorized to develop an APA award fund using the unrestricted funds in the grants and awards account and the funds currently in the special purposes account to help fund existing awards and to establish new awards where appropriate.

The Council received the reports of the several award boards, including the *Hofheimer Prize Board*, the *Vestermark Prize Board*, the *McGavin Award Selection Board*, and the *Hospital & Community Psychiatry Service Achievement Awards Board*, whose selections will be publicly announced at the appropriate times.

Dr. Greenblatt would like to express his appreciation to Dr. Jack White, staff liaison, and to the Council members for their enthusiastic efforts.

The Council on Emerging Issues

JERRY M. LEWIS, M.D., CHAIRPERSON

THE COUNCIL HELD three meetings during the past year. Two task forces of the Council continue to work on reports that will soon be ready for the Council's review. These are the *Task Force on Psychosurgery*, John Donnelly, M.D., chairperson, and the *Task Force to Define Mental Illness and "What is a Psychiatrist?"*, Morton Reiser, M.D., chairperson.

The *Task Force on Psychohistory*, Charles K. Hofling, M.D., chairperson, completed its report in 1974; it was unanimously approved by the Council for publication and was also approved by the Reference Committee and sent to the Board of Trustees. On December 6, 1975, the Board declined to authorize its publication as an APA task force report, giving the task force permission to publish it elsewhere. The Council on Emerging Issues continues to believe that the report is a scholarly and thoughtful document that should be available to all who are concerned about the issues of psychohistory and psychoprofiling.

The Council received a request from the Assembly of District Branches to prepare a charge for a national commission on the chronic psychotic patient. This issue has been discussed by the Council and additional information is being gathered from other agencies concerned with the welfare of the chronic psychotic patient.

A wide variety of emerging issues has been studied by the Council. These include the psychiatric aspects of decision making in the area of the dying patient, the lack of standards for sex therapy clinics, the current status of antipsychiatry groups, the variables involved in the increased number of assassination attempts, the misuse of psychiatry for political purposes, and changing suicide and homicide rates. The Council has also discussed at length the relationship of increased unemployment to mental health. A panel on this subject has been arranged for the 1976 annual meeting and will be chaired by Perry Ottenberg, M.D., vice-chairperson of the Council.

The Council plans to monitor a small number of task forces in order to have adequate time available to discuss a wide variety of emerging issues. From time to time the Council will recommend the formation of a task force regarding such an issue but will frequently ask that such task forces be affiliated with other Councils.

The Assembly of District Branches

AS 1975 BEGAN, the Key Conference was being actively planned, and the Assembly worked hard to make sure that there would be a good geographic distribution and representation of its members at the March session. Since many of the events leading up to the Key Conference stemmed from a decade-long concern in the Assembly about the governance of the organization, it was felt that the Assembly should be well represented. When the Assembly *Task Force on the Key Conference Recommendations* was appointed at the annual meeting in May, it began actively discussing both the structure of the Assembly and its relationship to other components of the organization.

The Procedural Code was reorganized during the summer and approved by the Assembly at its fall meeting. The Task Force on the Key Conference Recommendations continued to work out procedural relationships with the Board of Trustees. A Joint Conference Committee, whose penultimate meeting was scheduled for December 1975, began to finalize proposals to be incorporated in the proposed amendments to the Constitution.

Other committees of the Assembly reflected changes. The *Nominating Committee* faced the prospect of greater responsibility and the need to become more sophisticated in its processes. This committee is currently discussing the requirements of future candidates to submit written position statements and written responses to questions for publication in the election issue of *Psychiatric News*. There are also new proposals from the Key Conference on elections for representatives, better organized slates for area trustees, etc.

The *Membership Committee* has also been increasingly active. Representation on the APA Membership Committee reflects the concerns and ideas of younger members of the Assembly in assisting district branches, revising the pamphlet for prospective members, etc.

The Assembly *Budget Committee* will face new tasks during the coming year. The budget of the Assembly has never been thoroughly studied, and it will have to be totally reorganized in keeping with the changed responsibilities of the Assembly.

The *Task Force on Delivery of Mental Health Services* has

continued to work closely with the APA Committee on Financing of Mental Health Care and participated in the final report of that committee. Also, the task force has continued to support a three-tiered model of psychiatric peer review as developed by the APA Committee on Peer Review. Financing has been provided for a member of the APA Committee on Peer Review to visit district branches to aid them in establishing or improving their peer review process.

The *Rules Committee* is an increasingly important committee of the Assembly. At the May 1975 annual meeting the committee was extremely valuable in organizing the presentation of action papers. The Rules Committee continued to operate at the fall meetings, but the pressure of business, primarily related to the Key Conference, was so great that the Assembly was not able to complete its task properly.

The *Task Force on an Insurance Coding Project* was appointed by the Assembly to implement in several district branches a field trial of a coding system for psychiatric illness. This has been developed by the APA Task Force on Confidentiality in Relation to Third Party Payments. The Assembly requested that there be a trial in three areas, Northern and Southern California, Connecticut, and Wisconsin. Since it will be essential to include participation of the "Blues," the Assembly suggested that the trial might also include the use of Procedural Terminology for Psychiatrists. The pilot study will be in the form of a research project removed from the actual claims-settling process. The task force will continue to confer with insurance representatives and maintain liaison with other Assembly and APA components engaged in parallel endeavors.

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

MAY BE AN APPROPRIATE CHOICE FOR YOUR NEXT PATIENT WITH CLINICAL DEPRESSION/ANXIETY

See Brief Summary on last page of advertisement for information on adverse reactions, contraindications, warnings and precautions.

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and
ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

Proved efficacy in the treatment of clinical depression/anxiety

In the five years since its introduction, Sinequan (doxepin HCl) has objectively demonstrated its value in the treatment of clinical depression/anxiety. Clinical studies have shown Sinequan to be unsurpassed in effectiveness when compared to other tricyclic antidepressants.

In addition, Sinequan may offer certain advantages not generally seen with some other drugs of its class:

Marked antianxiety activity

In addition to its significant antidepressant activity, which is usually seen two to three weeks after initiation of therapy, Sinequan possesses marked antianxiety activity.

In double-blind comparisons between doxepin and amitriptyline,[1-3] the antidepressant effects of both drugs were comparable; however, more notable antianxiety effects were seen with doxepin. Superior antianxiety activity was reported among depressed patients treated in a crisis intervention clinic.[4]

Prompt sedative activity

Of the tricyclic antidepressants, Sinequan has been found to have one of the most prominent sedative effects.[5] This sedative property can be taken advantage of by administering the major portion of the daily dose *h.s.* Since clinically depressed/anxious patients frequently have accompanying sleep disturbances, this may be a valuable benefit.

Generally does not affect the activity of guanethidine at usual clinical doses[6]

"A new tricyclic antidepressant, doxepin, was evaluated for its ability to block the amine uptake mechanisms of the peripheral adrenergic neuron and blood platelet in man. At low doses, there was no evidence of inhibition of the amine pump." At clinical dosages up to 150 mg. per day, Sinequan can be given to man concomitantly with guanethidine and related compounds without blocking the antihypertensive effect.[6]

Cardiovascular side effects reported infrequently

In a series of double-blind comparative studies, 1706 doxepin-treated patients were evaluated for side effects. Incidence of tachycardia was associated with only 45 (2.6%) clinically depressed/anxious patients.[3]

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and
ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, paresthesias, ataxia, and extrapyramidal symptoms.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, facial edema, photosensitization, pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, and anorexia have been reported. (See anticholinergic effects).

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice and alopecia have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

As an alternative regimen, the total daily dosage, up to 150 mg., may be given on a once-a-day schedule without loss of effectiveness. This dose may be given at bedtime.

Anti-anxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.

Supply. Available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). SINEQUAN (doxepin HCl) 25 mg. and 50 mg. also available in bottles of 5000. SINEQUAN Oral Concentrate (10 mg./ml.) is available in 120 ml. bottles with an accompanying dropper calibrated at 5 mg., 10 mg., 15 mg., 20 mg., and 25 mg. SINEQUAN Oral Concentrate should be diluted with approximately 120 ml. of water or orange juice prior to administration.

Loxitane®
LOXAPINE SUCCINATE
Lederle

Exhibited certain favorable trends in side effects profile

IN 31 STUDIES INVOLVING 469 ACUTE AND CHRONIC SCHIZOPHRENIC PATIENTS, CERTAIN FAVORABLE TRENDS WERE EXHIBITED IN THE LOXITANE SIDE EFFECTS PROFILE; THESE REQUIRE FURTHER TESTS AND BROADER CLINICAL EXPERIENCE FOR CONFIRMATION.

While cardiac arrest, blood dyscrasias and renal toxicity have been reported with other antipsychotic agents, they have not been seen with LOXITANE. Hepatotoxicity manifested by jaundice or biliary stasis has not been observed. Transient liver enzyme changes, however, have been reported, but it has not been determined whether they are related to LOXITANE administration.

Although a few cases of changes in ECG have been reported, a causal relationship between this reaction and LOXITANE has not been established. Clinical experience with LOXITANE has not demonstrated ocular toxicity; however, the possibility of its occurrence cannot be ruled out at this time. Of the various endocrine abnormalities, only galactorrhea has been reported with LOXITANE and only in rare instances. Manifestations of adverse effects on the central nervous system other than extrapyramidal symptoms have been encountered infrequently, and drowsiness, when it occurs, is usually mild and subsides with continued therapy. Skin rashes of uncertain etiology have been observed in a few patients during the hot summer months; therefore the possibility of phototoxicity and/or photosensitivity cannot be excluded.

In general, LOXITANE presents a profile of extrapyramidal side effects similar to that of other agents used in the treatment of schizophrenia.

Cardiovascular effects such as hypotension, hypertension, lightheadedness and syncope have been reported. Anticholinergic effects seen with LOXITANE include dry mouth, nasal congestion, constipation and blurred vision.

arnings and precautions and for more detailed information concerning side effects.

FOR ORAL USE

PRODUCT INFORMATION

DESCRIPTION

LOXITANE *loxapine*, a dibenzoxazepine compound, represents a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines. Chemically, it is 2 - chloro - 11 - (4 - methyl - 1 - piperazinyl) dibenz [b,f] [1,4] oxazepine. It is present in capsules as the succinate salt. Each 1.36 mg of loxapine succinate is equivalent to 1 mg of loxapine.

ACTIONS

Pharmacologically, loxapine is a tranquilizer for which the exact mode of action has not been established. However, changes in the level of excitability of subcortical inhibitory areas have been observed in several animal species in association with such manifestations of tranquilization as calming effects and suppression of aggressive behavior.

In normal human volunteers, signs of sedation were seen within 20 to 30 minutes after administration, were most pronounced within 1½ to 3 hours, and lasted through 12 hours. Similar timing of primary pharmacologic effects was seen in animals.

Absorption of loxapine following oral or parenteral administration is virtually complete. The drug is removed rapidly from the plasma and distributed in tissues. Animal studies suggest an initial preferential distribution in lungs, brain, spleen, heart, and kidney. Loxapine is metabolized extensively and is excreted mainly in the first 24 hours. Metabolites are excreted in the urine in the form of conjugates and in the feces unconjugated.

INDICATIONS

LOXITANE *loxapine succinate* is indicated for the manifestations of schizophrenia.

CONTRAINDICATIONS

LOXITANE is contraindicated in comatose or severe drug-induced depressed states (alcohol, barbiturates, narcotics, etc.)

LOXITANE is contraindicated in individuals with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy: Safe use of LOXITANE *loxapine succinate* during pregnancy or lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the benefits of treatment be weighed against the possible risks to mother and child. No embryotoxicity or teratology was observed in studies in rats, rabbits or dogs, although with the exception of one rabbit study, the highest dosage was only two times the maximum recommended human dose and in some studies they were below this dose. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from midpregnancy with doses of 0.6 and 1.8 mg/kg, doses which approximate the usual human dose but which are considerably below the maximum recommended human dose.

Usage in Children: Studies have not been performed in children; therefore this drug is not recommended for use in children below the age of 16.

LOXITANE, like other tranquilizers, may impair mental and/or physical abilities, especially during the first few days of therapy. Therefore, ambulatory patients should be warned about activities requiring alertness (eg, operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

PRECAUTIONS

LOXITANE loxapine succinate should be used with extreme caution in patients with a history of convulsive disorders since it lowers the convulsive threshold. Seizures have been reported in epileptic patients receiving LOXITANE at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy.

Loxapine has an antiemetic effect in animals. Since this effect may also occur in man, loxapine may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

LOXITANE should be used with caution in patients with cardiovascular disease. Increased pulse rates have been reported in the majority of patients receiving antipsychotic doses; transient hypotension has been reported. In the presence of severe hypotension requiring vasopressor therapy, the preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine.

The possibility of ocular toxicity from loxapine cannot be excluded at this time. Therefore, careful observation should be made for pigmentary retinopathy and lenticular pigmentation since these have been observed in some patients receiving certain other antipsychotic drugs for prolonged periods.

Because of possible anticholinergic action, the drug should be used cautiously in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinson medication.

ADVERSE REACTIONS

CNS Effects: Manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently. Drowsiness, usually mild, may occur at the beginning of therapy or when dosage is increased.

It usually subsides with continued LOXITANE therapy. The incidence of sedation has been less than that of certain aliphatic phenothiazines and slightly more than the piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported.

Extrapyramidal Reactions—Neuromuscular (extrapyramidal) reactions during the administration of LOXITANE *loxapine succinate* have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved Parkinson-like symptoms such as tremor, rigidity, excessive salivation, and masked facies. Akathisia (motor restlessness) also has been reported relatively frequently. These symptoms are usually not severe and can be controlled by reduction of LOXITANE dosage or by administration of antiparkinson drugs in usual dosage. Dystonic and dyskinetic reactions have occurred less frequently, but may be more severe. Dystonias include spasms of muscles of the neck and face, tongue protrusion, and oculogyric movement. Dyskinetic reaction has been described in the form of choreo-athetoid movements. These reactions sometimes require reduction or temporary withdrawal of LOXITANE dosage in addition to appropriate counteractive drugs.

Persistent Tardive Dyskinesia—As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movement of the tongue, face, mouth, or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinson agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Cardiovascular Effects: Tachycardia, hypotension, hypertension, light-headedness, and syncope have been reported.

A few cases of ECG changes similar to those seen with phenothiazines have been reported. It is not known whether these were related to loxapine administration.

Skin: Dermatitis, edema (puffiness of face), pruritus, and seborrhea have been reported with loxapine. The possibility of photosensitivity and/or phototoxicity occurring has not been excluded; skin rashes of uncertain etiology have been observed in a few patients during hot summer months.

Endocrine Effects: No endocrine abnormalities have been reported.

Anticholinergic Effects: Dry mouth, nasal congestion, constipation, and blurred vision have occurred; these are more likely to occur with concomitant use of antiparkinson agents.

Other Adverse Reactions: Nausea, vomiting, weight gain, weight loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, and polydipsia have been reported in some patients.

DOSAGE AND ADMINISTRATION

LOXITANE *loxapine succinate* is administered orally usually in divided doses two to four times a day. Daily dosage (in terms of base equivalents) should be adjusted to the individual patient's needs as assessed by the severity of symptoms and previous history of response to antipsychotic drugs. Initial dosage of 10 mg twice daily is recommended, although in severely disturbed patients initial dosage up to a total of 50 mg daily may be desirable. Dosage should then be increased fairly rapidly over the first seven to ten days until there is effective control of psychotic symptoms. The usual therapeutic and maintenance range is 60 mg to 100 mg daily. However, as with other antipsychotic drugs, some patients respond to lower dosage and others require higher dosage for optimal benefit. Daily dosage higher than 250 mg is not recommended. For maintenance therapy, dosage should be reduced to the lowest level compatible with symptom control; many patients have been maintained satisfactorily at dosages in the range of 20 mg to 60 mg daily.

HOW SUPPLIED

LOXITANE *loxapine succinate* is supplied in the following base equivalent strengths:

CAPSULES Hard Shell Printed "Lederle"

10 mg—Green and Yellow; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5360.

25 mg—Green Two Tone; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5361.

50 mg—Green and Blue; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5362.

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

80pp. Paperbound

Single copy, $4.00; 10–49 copies; $3.80 each; 50 or more copies, $3.20 each.

SPECIAL OFFER: One copy of this book (regular price, $4.00) and one copy of **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (regular price, $6.50) for $8.50.

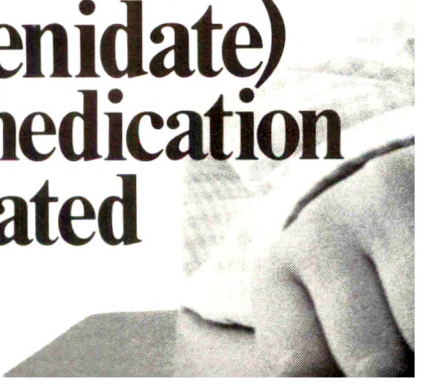
Tested by time and experience in

1962

"...a considerable decrease of hyperactivity...."[1] Knobel, 1962

Over a decade of controlled studies and clinical experience has shown the effectiveness of Ritalin in reducing the hyperactivity,[1-3] distractibility,[1,4,5] and disorganized behavior[1-8] in the MBD child.

By lessening the effects of motor and attentional disorders, Ritalin can help the MBD child to better focus his attention on meaningful stimuli and thus can often improve cognition and promote learning.[6,9]



And side effects – insomnia and appetite loss – with Ritalin have occurred less frequently than with dextroamphetamine.[10,11]

Indeed, Ritalin is currently a drug of choice in many MBD situations,[10,12] and can prove to be an important element in many complete remedial programs for MBD.

Therapy with Ritalin should be undertaken only after a medical diagnosis of MBD has been made. Drug treatment is not indicated for all children with MBD.

Dosage should be periodically interrupted. Often, these interruptions reveal some "stabilization" in the child's behavior even without medication, permitting a reduction in dosage and eventual discontinuance of drug therapy.

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

CHARLES C THOMAS • PUBLISHER

CONTROVERSIAL ISSUES IN HUMAN RELATIONS TRAINING GROUPS *edited by* **Kenneth T. Morris,** *Central Michigan Univ., Mount Pleasant, and* **Kenneth M. Cinnamon.** *Foreword by* **Mike Kanitz.** *(7 Contributors)* Controversial issues covered deal with such group dynamics variables as certification of group leaders, sex between members, necessary leader skills, necessary variables required for a successful group, the place of physical contact and structured experiences, screening of members, bias in group orientation and format, and whether these training groups are an art or a science. Each issue comprises one chapter with an editor's summary and synopsis section at the end. *'75, 168 pp., cloth-$9.75, paper-$5.95*

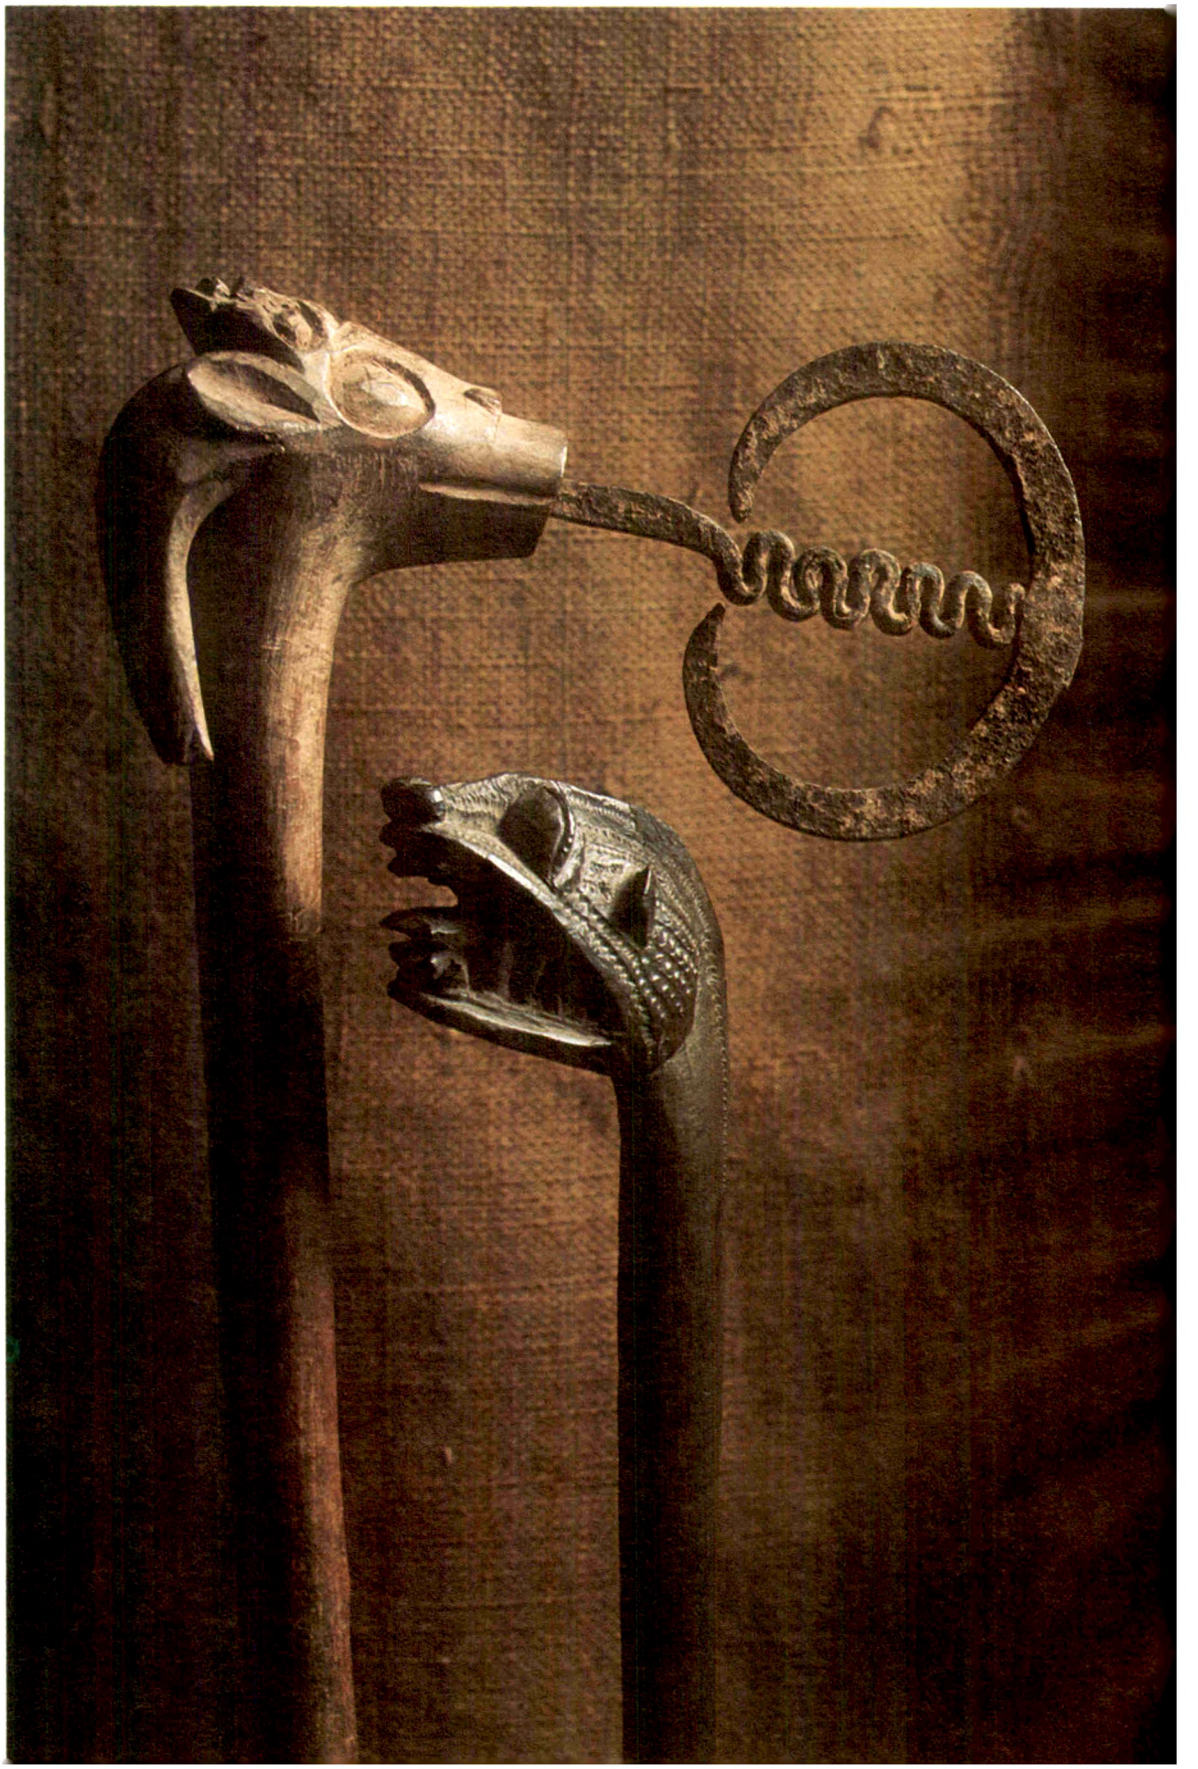
CLINICAL USE OF PSYCHOTHERAPEUTIC DRUGS (3rd Ptg.) *by* **Leo E. Hollister,** *Stanford Univ. School of Medicine, Palo Alto, California.* Clinical experience with the use of drugs in the treatment of patients is related to their pharmacological properties that bear most directly on their application to the treatment of emotional disorders in man. Each class of drugs is considered in relation to the chemical and pharmacological differences among its members, pharmacological properties and pharmacokinetics as they relate to their clinical use, specific clinical indications, general principles of use, use in combination with other drugs, and their side effects and toxicology. Antipsychotic, antimanic, antidepressant and antianxiety drugs are all closely examined. *'75, 192 pp., 11 il., 13 tables, $7.95*

LIFE STRESS AND ILLNESS *edited by* **E. K. Eric Gunderson,** *Univ. of California, San Diego, and* **Richard H. Rahe,** *Univ. of California, Los Angeles. (19 Contributors)* Relationships between stressful life events and various types of illness including mental illness and heart disease are examined in this book. Major emphasis is placed on the development of quantitative techniques for the measurement of life stress and the scaling of specific life events which have specific significance for the onset of disease. The physiological and psychological effects of severe stresses, such as prisoner of war confinement, are described, but the effects of milder stresses of everyday living are considered as well. The importance of cultural differences in determining the kinds of social stresses typically encountered in an individual's life are also illustrated. *'74, 276 pp., 25 il., 27 tables, $19.50*

CHILDREN'S EXPERIENCE WITH DEATH *by* **Rose Zeligs,** *Sherman Oaks, California.* This book shows how the child and adolescent is affected by his experience with death. Every chapter contains topical headings, a summary, and a list of references to make teaching and learning easier. Chapters cover developmental concepts of death, fear of death, the hospital experience of the dying child and adolescent, the handicapped child, suicide among children and adolescents, the death of a parent, and the influence of religion on his attitudes toward death. The author talks with children and listens to them, bringing a better understanding of children's ideas, attitudes, and feelings about death. *'74, 264 pp., $10.75*

SELF-DESTRUCTIVE BEHAVIOR *compiled and edited by* **Albert R. Roberts,** *Coppin State College, Baltimore, Maryland. (14 Contributors)* New insights concerning chronic risk-taking behavior and the heightening of coping mechanisms are provided in this book. Social, psychological, medical and psychiatric correlates of the most prevalent forms of self-destruction are all taken into account. Suicidal and subsuicidal behaviors such as the one-car accident, drug-related deaths, homicide followed by suicide, chronic alcoholism and cirrhosis of the liver, and cardiovascular diseases and diabetes mellitus exacerbated by compulsive overeating are described. In addition, the authors have made reference to the commonalities and causal links between many of these self-destructive acts. *'75, 232 pp., 9 il., 7 tables, $17.50*

INVOLUNTARY TREATMENT OF THE MENTALLY ILL: The Problem of Autonomy *by* **Michael Alfred Peszke,** *Univ. of Connecticut School of Medicine, Hartford.* This review puts the problem of involuntary treatment of mental illness into historical perspective and looks at it objectively, recognizing that mental illness cannot simply be legislated out of existence. The author suggests implementation for meeting the needs of the mentally ill based on the right of everyone to his own autonomy. Suggestions are proposed, leading to a situation in which no one in our society will be deprived of enlightened and appropriate treatment, while no one is deprived of freedom in a thoughtless or arbitrary fashion. *'75, 176 pp., 1 il., $10.75*



THE PROMISCUOUS TEENAGER *by* **Daniel T. Gianturco** *and* **Harmon L. Smith,** *both of Duke Univ., Durham, North Carolina.* Psychiatric guidelines are provided to understand why teenage sexual behavior is promiscuous or healthly. Teenage sexuality is viewed with the assumption that sexual activity involves important decision-making for a comprehensive cluster of interested and involved persons including teenagers, their parents and physicians. Ethical concepts are introduced to develop an integrated view of teenage sexual decision making. Sexual topics discussed include marriage, communal living, homosexuality, pregnancy, abortion, and contraception. Suggestions are included for management of the sexually disturbed teenager. *'74, 128 pp., 14 il., $8.50*

PSYCHIATRIC ASSESSMENT BY SPEECH AND HEARING BEHAVIOR *by* **Clyde L. Rousey,** *The Menninger Foundation, Topeka, Kansas. Foreword by* **J. Cotter Hirschberg.** *(18 Contributors)* Presentation of a theory of speech which has clinical relevance to the assessment of emotional health is the primary focus of this work. The studies cover such areas as diagnostic assessment of psychiatric patients, selection of trainees for residency programs in psychiatry, hearing problems in psychiatric patients, the phenomenon of speaking in tongues, early detection of educational problems resulting from emotional problems, factors affecting psychiatric diagnosis and treatment planning, and neurological indications in speech and hearing behavior. *'74, 392 pp., 12 tables, $18.75*

Basic tools of primitive psychiatry

Mankpo: Sceptres or staffs used by the Heviosso (lightning God) cult in medical ceremonies among the Ewe of Tongo and Fon of Dahomey. *Right,* staff with leopard's head, bared teeth and tongue (Ewe, Togo). *Left,* staff with ram's head—the sacred animal of the Heviosso—in the form of a serpent symbolizing the fire-spitting rainbow God of healing (Fon, Dahomey). From the collection of the Segy Gallery, New York City.

Basic tool of Western psychiatry

Thorazine®
(chlorpromazine, SK&F)

Tablets: 25 and 50 mg of the HCl

- 'Thorazine' controls psychotic symptoms
- Especially useful in agitated, violent or anxious schizophrenic patients
- Unsurpassed clinical experience
- 18 convenient dosage forms and strengths

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

For effective management of schizophrenic symptoms.

Suspicious and hostile?

Consider the advantages of starting her on HALDOL® (haloperidol)

Acts promptly to control hostility and suspiciousness

Several clinicians have cited the special value of HALDOL haloperidol in controlling hostility, suspiciousness, ideas of persecution and other delusions associated with psychoses.[1-6] Symptom control is achieved rapidly, with many patients showing distinct improvement in a few days to a week[1,6]—frequently within a few hours when the intramuscular form is used for initial control of acutely agitated psychotic states.[7,8]

Usually leaves patients relatively alert and responsive

Although some instances of drowsiness have been observed, marked sedation with HALDOL haloperidol is rare. In fact, this drug has been reported to increase activity in some underactive patients, while in hyperactive patients it usually reduces activity to a normal level without somnolence. HALDOL haloperidol has been found to "normalize" behavior and produce a sensitivity to the environment that allows more effective use of the social milieu and the therapeutic community.[4]

Reduces likelihood of certain adverse reactions

HALDOL haloperidol, a butyrophenone, avoids or minimizes many of the problems associated with the phenothiazines. The most commonly noted side effects of HALDOL haloperidol—extrapyramidal reactions—are usually dose-related and readily controlled with antiparkinson drugs.

Transient hypotension occurs rarely; severe orthostatic hypotension has not been reported. HALDOL haloperidol is also unlikely to cause hepatic damage, serious hematologic reactions, photosensitivity reactions and skin rashes. Ocular damage and pigmentation changes have not been reported.

HALDOL®
(haloperidol)
tablets/concentrate/injection

highly specific control of disordered and disruptive behavior

For information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions, please turn page.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

*McNeil Laboratories, Inc., 1975

HALDOL®
(haloperidol)
tablets/concentrate/injection

highly specific control of disordered and disruptive behavior

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

An undetectable, tasteless liquid concentrate for the patient unable or unwilling to swallow tablets: 2 mg. per cc.

A rapid-acting injection for psychiatric emergencies: 5 mg. per cc., with 0.5 mg. methylparaben and 0.05 mg. propylparaben per cc., and lactic acid for pH adjustment to 3.4±0.2.

Indications: HALDOL haloperidol is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's syndrome.

Contraindications: HALDOL haloperidol is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL haloperidol in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of haloperidol orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL haloperidol, decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL haloperidol may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL haloperidol should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL haloperidol may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant antiparkinson medication is required, it may have to be continued after HALDOL haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson agents, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of antiparkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long-term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed. 9/74

McNEIL McNeil Laboratories, Inc.
Fort Washington, Pa. 19034

Schering

Out of touch

but not beyond reach...

Help restore reality

- low dose, high potency phenothiazine useful for inpatient and outpatient treatment
- helps orient psychiatric patients to their surroundings
- effective with minimal sedation, usually produces little lethargy or drowsiness

Trilafon®
brand of
perphenazine, NF
for management of disturbed behavior in schizophrenic and manic states

Versatile Dosage	
Injection	5 mg/ml, 1 ml ampul
Concentrate	16 mg/5 ml, 120 ml bottle
Tablets	2,4,8,16 mg
REPETABS® Tablets 8 mg brand of repeat-action tablets	

Please see next page for prescribing information.

Trilafon®
brand of
perphenazine, NF

For management of schizophrenic and manic disorders in psychiatric hospitals, mental health clinics, and with outpatient treatment

TABLETS
for maintenance or control of patients in hospital or home

BENEFITS

- generally improve cooperation and communication
- decrease need for custodial care, hasten discharge

CONCENTRATE
for maintenance or control of uncooperative in-hospital patients

- easily mixes with most liquids
- ensures easy, steady, certain administration

INJECTION
for emergency control of uncooperative in-hospital patients

- usually takes effect in 10 minutes
- average duration of effect is 6 hours

TRILAFON® Tablets
brand of perphenazine, NF
REPETABS® Tablets
Concentrate
Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON **Injection** should not be given to patients in coma or severely depressed states.

WARNINGS **Dosage in pregnancy:** Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operating machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenazine should be under medical supervision, particularly if they are receiving high doses. Patients who have had any severe reaction to phenothiazines or to imipramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patients treated with perphenazine, the possibility that they might occur with TRILAFON should be considered: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the visual fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyphagia; photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, but not epinephrine, because epinephrine's action is blocked and partly reversed by perphenazine. Severe, acute hypotension has occurred with the use of phenothiazines and is of particular concern in patients with mitral insufficiency or pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic reaction to perphenazine; treatment with perphenazine should be stopped if this occurs.

The antiemetic effect of perphenazine can obscure signs of toxicity due to overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor or intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefore, contact of hands or clothing by those handling perphenazine solutions should be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-system-depressant actions of opiates, antihistamines, barbiturates, and alcohol, less than the usual dosage of these agents is required when they are administered concomitantly with TRILAFON. Patients should be cautioned that their response to alcohol may be increased while they are being treated with TRILAFON.

Phenothiazines also potentiate the effects of atropine, heat, and phosphorus insecticides, and should be used with caution in persons exposed to these agents.

ADVERSE REACTIONS *Extrapyramidal reactions:* dystonia including protrusion, discoloration, aching and rounding of the tongue; tonic spasm of the masticatory muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric crisis, trismus, torticollis, retrocollis, muscle weakness, and aching and numbness of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; hyperreflexia; and ataxia. The incidence and severity of these reactions usually increase with increased dosage, but have occurred in some patients receiving low dosage. Reduction in dosage or treatment with an antispasmodic agent will usually control extrapyramidal reactions. In some instances, however, these reactions may persist after discontinuation of treatment with perphenazine.

Persistent tardive dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities. There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine, vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON **Injection** have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON (perphenazine) **Injection** is a rare occurrence.

No default insurance

Tofranil-**PM**®
imipramine **pamoate**

Geigy

In depression

Daily Dosage Chart

1 h.s.

A major reason for drug defaulting is multiple daily dosage schedules.

Ayd* reports that 70 percent of patients default on a q.i.d. regimen; 60 percent on t.i.d.; 30 percent on b.i.d., and only 7 percent on a single daily dose.

A single daily capsule that provides a full day's medication would logically assure better therapeutic results.

Because one capsule lasts from bedtime to bedtime, Tofranil-**PM**® may markedly reduce the probability of missed doses.

After therapy is initiated with the 75-mg. capsule, the 150-mg. capsule is the dose level at which optimum response is usually obtained.

Please review the prescribing information summarized on the back of this page.

*Ayd, F.J., Jr. (Ed.): Int. Drug Ther. Newslett. 7(9/10):35-50 (Nov./Dec.) 1972.

Tofranil-PM®
imipramine **pamoate**

One capsule lasts from bedtime to bedtime.

Initial Dose		For Maintenance Therapy			
Starting Dose	Usual Optimum Response Dose	A Full Range to Choose From*			
					
75 mg.	150 mg.	150 mg.	125 mg.	100 mg.	75 mg.

*Each capsule contains imipramine pamoate equivalent to 150, 125, 100 or 75 mg. imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;

—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;

—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;

—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;

—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response.If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks. Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

4th edition

A Psychiatric Glossary

Edited by a subcommittee of the AMERICAN PSYCHIATRIC ASSOCIATION Committee on Public Information.

The new Fourth Edition marks a striking expansion of definitions: 400 terms have been added and many of the terms appearing in earlier editions have received revised explanations. In addition to the GLOSSARY's continuing value to lawyers, teachers, journalists, social workers, and others, the new edition will be useful to medical students and first year residents in psychiatry.

Some major changes in the Fourth Edition:

- Expansion from 102 to 156 pages to accommodate 400 new terms
- New tables of terms in seven areas of contemporary concern
  - Drugs Used in Psychiatry
  - Legal Terms
  - Neurologic Deficits
  - Psychological Tests
  - Research Terms
  - Schools of Psychiatry
  - Sleep Disorders
- A comprehensive set of terms used in behavior therapy is included for the first time.

Paperback edition—$3.00 each, (See coupon for bulk discounts), may be ordered from the AMERICAN PSYCHIATRIC ASSOCIATION, Publications Sales, 1700 18th St. N.W., Washington, D.C. 20009.

Hardback edition—$7.95 may be ordered from Basic Books, Inc., 10 East 53rd Street, New York, New York 10022.

What can a long-acting injectable phenothiazine do that a short-acting oral can't?

It can save time, it can save money, and it can even save people – by reducing readmissions.

Time Prolixin Decanoate (Fluphenazine Decanoate Injection), with duration of action that may last up to 4 weeks or longer in patients on maintenance therapy, can effect important savings in nursing time.

Approximate Staff Time Required to Medicate 18 Schizophrenic Patients*

8 a.m. ¾ hr. 4 p.m. ¾ hr. 8 p.m. ¾ hr.	1 injection every 28 days for most patients
= 2¼ hours nursing time	4 minutes required for each injection
2¼ hrs. x 28 days = 63 hours of nursing time every 28 days	= 1 hr., 10 minutes nursing time in 28 days
NURSING TIME SAVED IN 28 DAYS	61 hours and 50 minutes or more than 7½ eight-hour working days

*Adapted from Platt R: Br J Social Psychiatry 2: 187-191, 1968.

Money Martin and Townend[1], who found from their study of Prolixin Decanoate that 15 of 39 patients could be maintained on 25 mg. every 4 weeks, also note that on this basis "a year's maintenance on chlorpromazine represents the order of 110 grams of phenothiazine as opposed to 0.33 gram of fluphenazine." Translating this into dollars shows the following potential hospital savings on the basis of patient population:

Agent and amount/year	Form	Cost/patient/ year	Cost/500 patients/ year
Chlorpromazine (SKF brand) 110 grams	8 oz. concentrate 100 mg./ml.†	$48.75*	$24,375
Prolixin Decanoate .33 grams	5 ml. vials 25 mg./ml.	23.17**	11,585
SAVINGS		$25.58 patient, year	$12,790 500 pts/yr.

* Calculated from prices published in 1975 Red Book.
** Calculated from Squibb 1975 price catalogue.
† With tablets, the annual cost is even greater.

People The controlled drug delivery system of Prolixin Decanoate helps get schizophrenic patients out of the hospital and helps them stay out. It promotes continuity of therapy—reducing outpatient drug defaulting from approximately 50% with oral medications according to one report[2] to about 16% according to another report[3].

It reduces the number and length of rehospitalizations. In one study of 103 patients maintained on injections of long-acting fluphenazines, total hospital readmissions for a year were cut from 191 to 50 and inpatient time from 8,713 days to 1,335 days[4].

It facilitates return to a productive life. A 12-month followup of 103 discharged patients revealed 77% in full-time employment or household duties and only 23% unemployed[4].

PROLIXIN DECANOATE®

(Fluphenazine Decanoate Injection)

may control schizophrenic symptoms for up to 4 weeks or longer in patients on maintenance therapy.

For product brief summary see following page.

H425-001R

PROLIXIN DECANOATE®

(Fluphenazine Decanoate Injection)

may control schizophrenic symptoms for up to 4 weeks or longer in patients on maintenance therapy.

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per ml. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety and efficacy in children have not been established because of inadequate experience in use in children.

Usage in Pregnancy: Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administering this drug to pregnant patients.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with a history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams; reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 ml. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 ml. vials.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

The vulnerable ages

The first epileptic seizure is most likely to occur during early childhood and at the onset of puberty

About 9 out of 10 epileptics experience their first seizure before the age of 20—with the highest incidence between 5 and 7, when children start school, and at the onset of puberty, a time of physiological and psychic turmoil.[1] The most common type, grand mal, occurs in approximately 75% of epileptic children,[1] and more than 50% of patients who suffer initially from petit mal develop grand mal seizures before they reach the age of 16.[2]

Mysoline (primidone) for control of grand mal, psychomotor and focal epilepsy

At the onset and afterwards — used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. *Excellent* for control of grand mal. Valuable for control of psychomotor[1,3,4] and focal epilepsy as well.[5]

Add Mysoline when control with other anticonvulsants is inadequate—As concomitant therapy, MYSOLINE can improve seizure control in grand mal and psychomotor epilepsy. The combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.[6]

Change to Mysoline when other anticonvulsants fail— A changeover to MYSOLINE is frequently warranted when other anticonvulsants must be discontinued because of important side effects, or when grand mal seizures are refractory to phenobarbital, with or without diphenylhydantoin.[7]

Mysoline® (primidone)

may be the start of a better life for the epileptic

initial and maintenance therapy for
grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY
(For full prescribing information, see package circular.)

MYSOLINE® Brand of PRIMIDONE
Anticonvulsant

ACTIONS: MYSOLINE acts on the central nervous system to raise seizure threshold or alter seizure pattern. The mechanism(s) of action of anticonvulsant drugs is not known.

Primidone has anticonvulsant activity *per se*. In addition, its two metabolites possess anticonvulsant qualities. The major metabolite is phenylethylmalonamide (PEMA); the other is phenobarbital. In addition to its own anticonvulsant potential, PEMA potentiates phenobarbital.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several days before it can be assessed.

Use in pregnancy: Recent reports strongly suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Reference has been made to primidone in several cases in which it was used *in combination* with other anticonvulsants; but its teratogenicity has not been conclusively demonstrated. The possibility exists that other factors, *e.g.*, genetic factors or the epileptic condition, may contribute to the higher incidence of birth defects. The data also indicate that the great majority of mothers receiving anticonvulsant medication deliver normal infants.

Anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and risk to both mother and the unborn child.

When the nature, frequency, and severity of the seizures do not pose a clear threat to the patient, good medical practice requires that the physician weigh the expected therapeutic benefit of anticonvulsant therapy against possible risk on an individual basis.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

The physician should weigh all of the foregoing considerations when treating and counseling epileptic women of childbearing potential.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

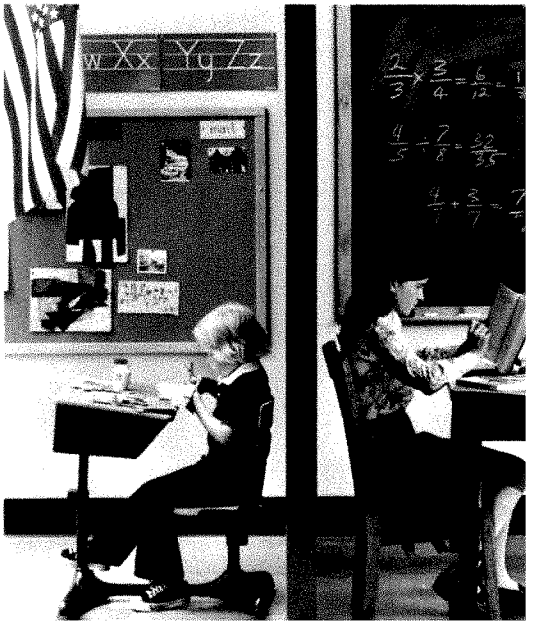
ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 mg. Increments of 250 mg. are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 Gm. A typical dosage schedule for the introduction of MYSOLINE (primidone) is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg., with gradual weekly increases of 125 mg. a day, to a daily total usually between 500 mg. and 750 mg.



In patients already receiving other anticonvulsants MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances:

- for initiation of combination therapy
- during "transfer" therapy
- for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.)

HOW SUPPLIED: MYSOLINE *Tablets* — No. 430 — Each tablet contains 250 mg. of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431 — Each tablet contains 50 mg. of primidone (scored), in bottles of 100 and 500. MYSOLINE *Suspension* — No. 3850 — Each 5 cc. (tea spoonful) contains 250 mg. of primidone, in bottles of 8 fluid ounces.

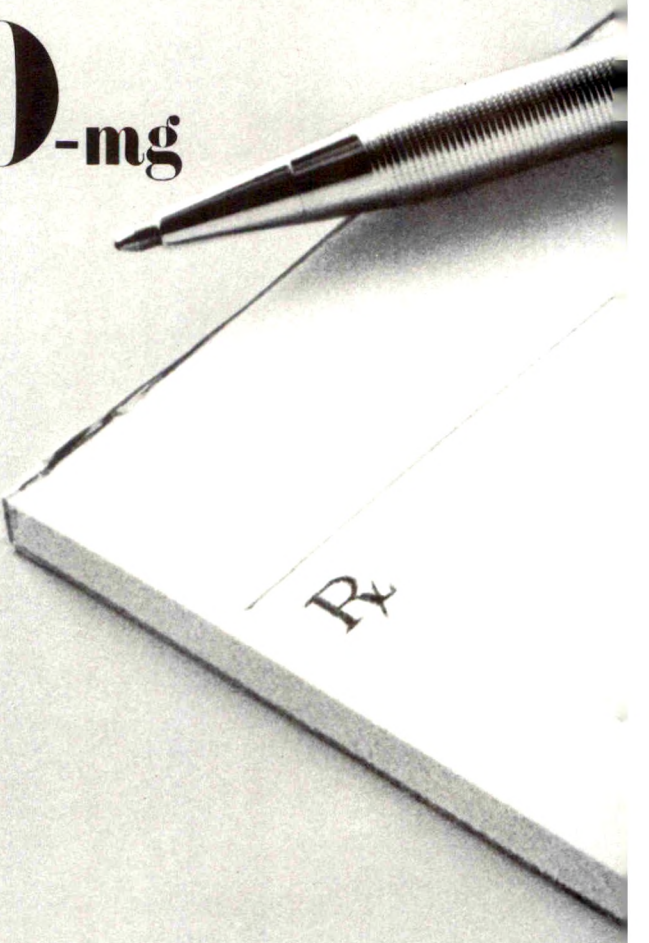
for clinically significant depression. . .

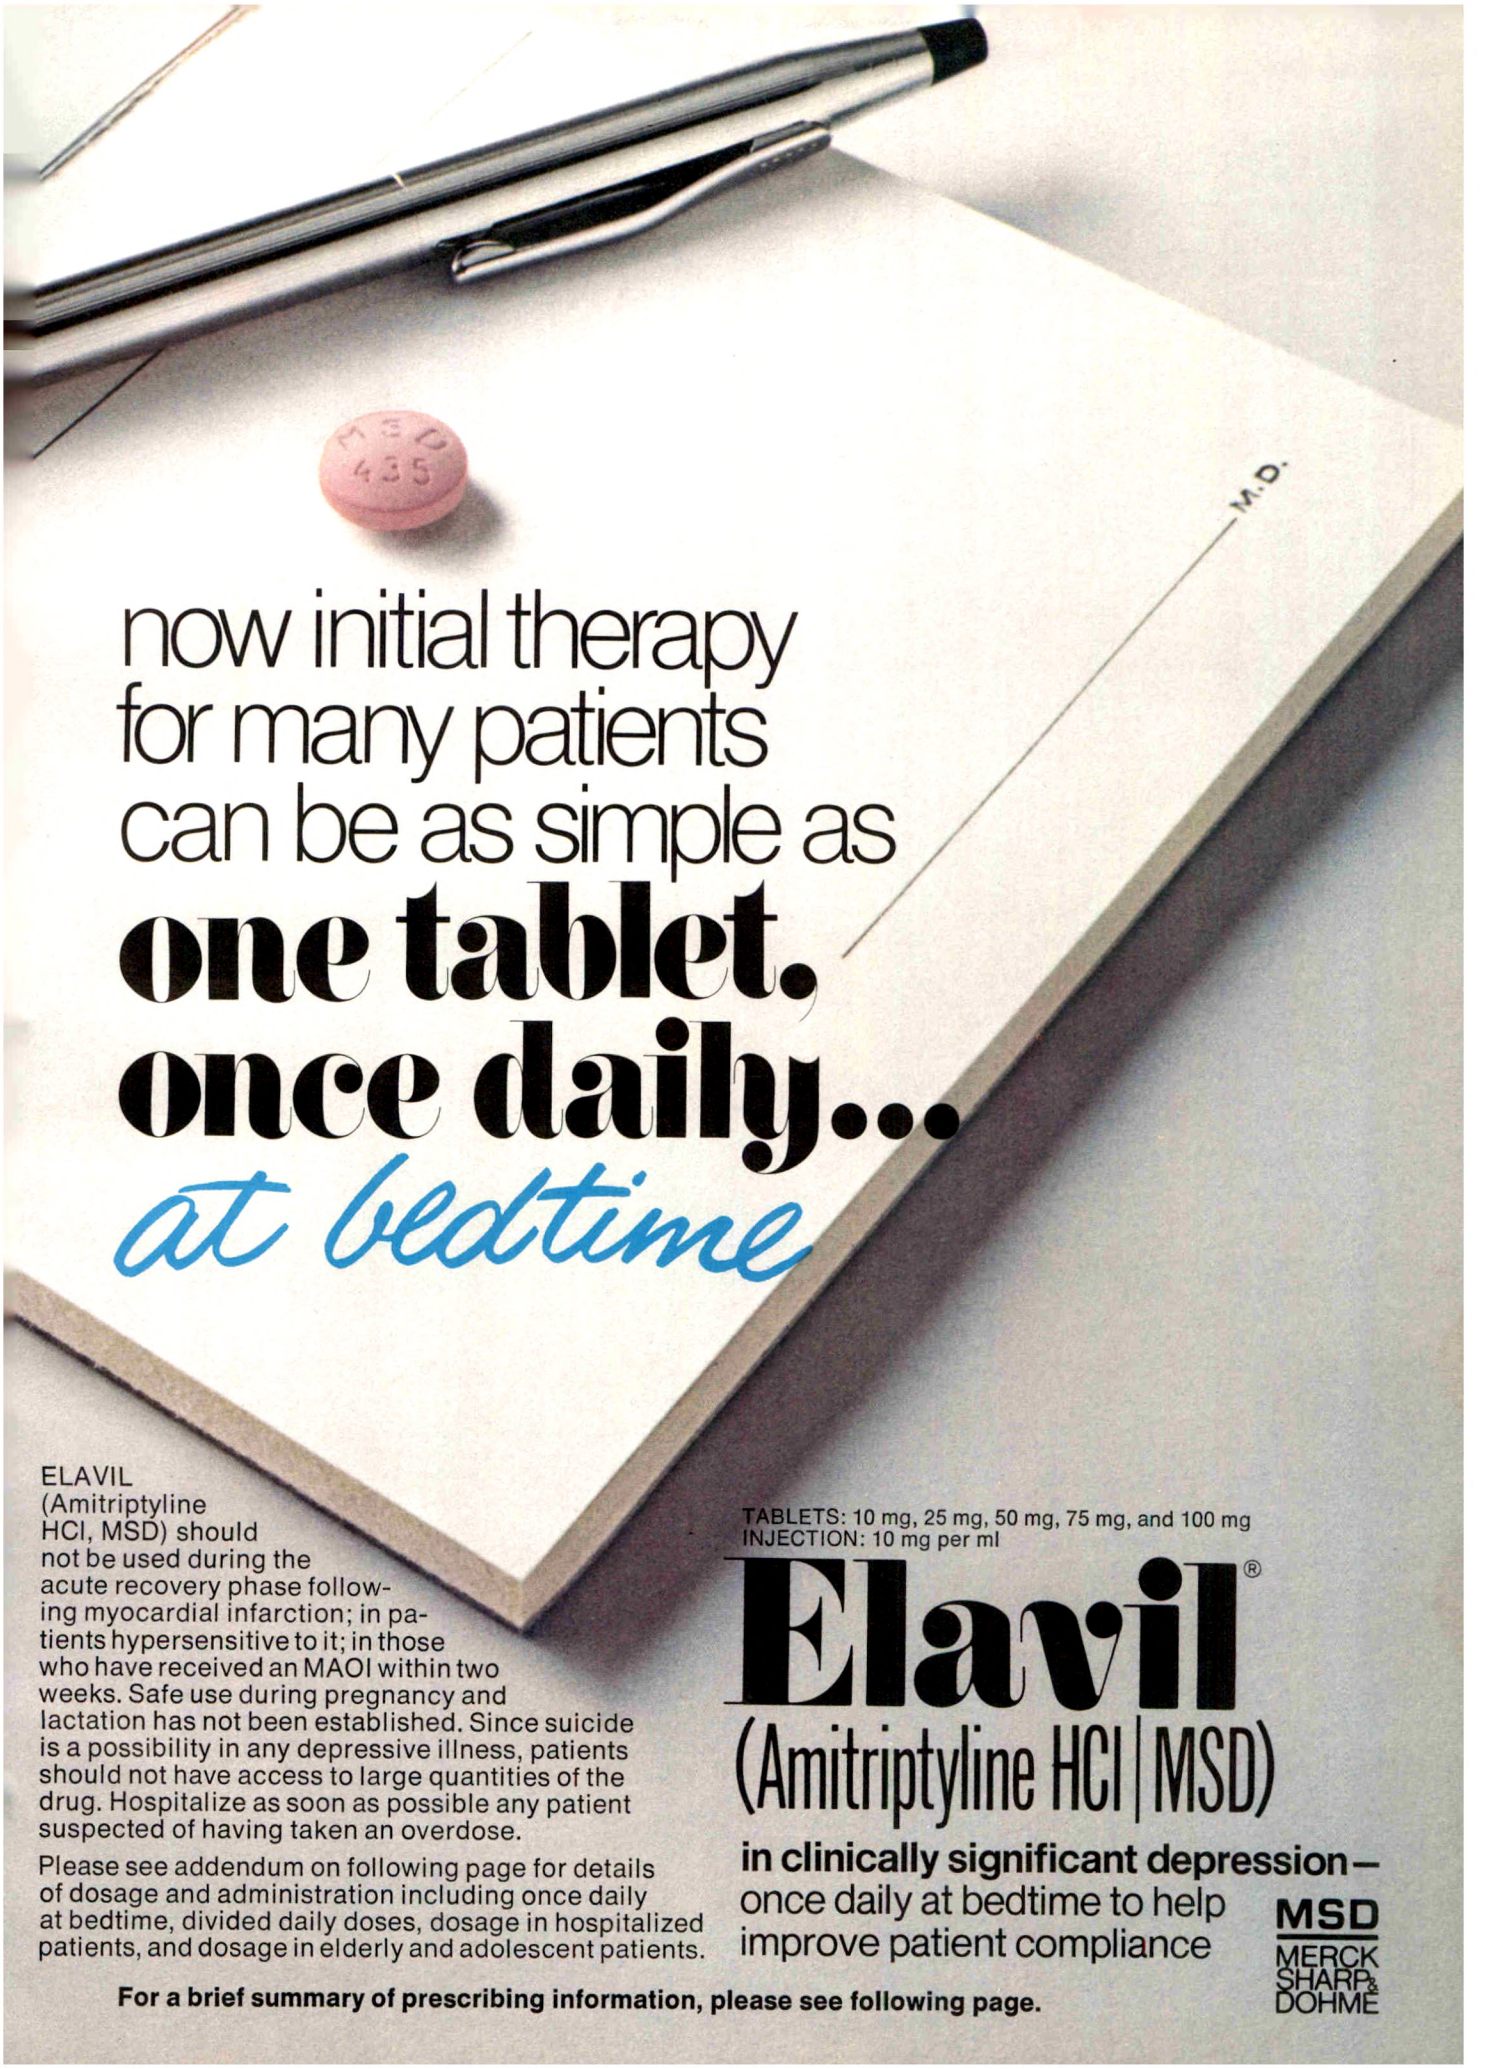
Merck Sharp & Dohme introduces

75- and 100-mg

TABLETS



Elavil®



(Amitriptyline HCl | MSD)

to further simplify once-daily

h.s.

therapy

now initial therapy for many patients can be as simple as **one tablet, once daily...** *at bedtime*

ELAVIL (Amitriptyline HCl, MSD) should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks. Safe use during pregnancy and lactation has not been established. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

Please see addendum on following page for details of dosage and administration including once daily at bedtime, divided daily doses, dosage in hospitalized patients, and dosage in elderly and adolescent patients.

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg
INJECTION: 10 mg per ml

Elavil®
(Amitriptyline HCl | MSD)

in clinically significant depression— once daily at bedtime to help improve patient compliance

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please see following page.

NEW TABLETS

Elavil®

(Amitriptyline HCl | MSD)

75 mg and 100 mg

to further simplify once-daily

h.s.

therapy

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: ***Note:*** Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. ***Cardiovascular:*** Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. ***CNS and Neuromuscular:*** Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. ***Anticholinergic:*** Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. ***Allergic:*** Skin rash, urticaria, photosensitization, edema of face and tongue. ***Hematologic:*** Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. ***Gastrointestinal:*** Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). ***Endocrine:*** Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. ***Other:*** Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. ***Withdrawal Symptoms:*** Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

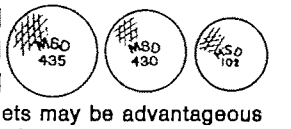
addendum

MSD
MERCK SHARP & DOHME

Elavil®

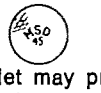


(Amitriptyline HCl | MSD)

Five tablet strengths for differing patient needs. The variety of dosage strengths available with ELAVIL makes possible great prescribing flexibility.

Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. The simplicity of this regimen helps improve patient compliance. ELAVIL may also be prescribed in divided daily doses.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.



100 mg
75 mg
50 mg

These tablets may be advantageous when initiating therapy with once-daily bedtime dosage in adult outpatients. The usual starting dosage is 75 mg daily. Therapy may be initiated with 50 to 100 mg daily. This may be increased by 25 or 50 mg as necessary in the bedtime dose to a total of 150 mg per day.

These tablets may also be convenient for many hospitalized patients. These patients may need 100 mg a day initially which can be increased gradually to 200 mg a day if necessary. A small number of such patients may need as much as 300 mg a day.

25 mg

This tablet may prove useful when initiating therapy with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime doses.

10 mg

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

PSYCHIATRIST DIRECTOR IN BOSTON

$25,407 to $28,441

The Dorchester Mental Health Center Unit of Boston State Hospital Area Program needs a Director for its 25 bed Inpatient service. This program is integrated with an extensive network of varied community programs.

Send resume to:

M. H. NELSON, M.D.
Superintendent/Area Program Director
Boston State Hospital
591 Morton St., Boston, Mass. 02124
Or call: (617) 436-6000, ext. 200, 201, 215

Equal Employment/Affirmative Action Employer

BOSTON STATE HOSPITAL
DORCHESTER MENTAL HEALTH CENTER

UNIT CHIEF — GRADE 32 (Psychiatrist III)
SALARY — $28,823.00 - $32,263.00

QUALIFICATIONS — Three years of residency training in Psychiatry, three years of paid professional, post-residential experience in the field of Psychiatry.

Dorchester Mental Health Center is a community unit of Boston State Hospital. The unit has a need for a Director who will be directly accountable to the Superintendent/ Area Program Director of Boston State Hospital.

Dorchester Mental Health Center serves the communities of Dorchester, Mattapan, and Neponset — a catchment area of approximately 100,000. The unit comprises an acute inpatient service, a longterm service, and an extensive community network of childrens and adult services.

Candidates should have strong commitment to the community mental health center model of delivery of services, have a demonstrated skill in administration, and program evaluation, and have an understanding of fiscal and budgetary matters. Skill in working with community members and community agencies is a necessity.

We are an equal employment opportunity employer.

All applications should be addressed in confidence to:

M.H. NELSON, M.D.
SUPERINTENDENT/AREA PROGRAM DIRECTOR
BOSTON STATE HOSPITAL
591 MORTON STREET
DORCHESTER, MASS. 02124

BOSTON STATE HOSPITAL
DORCHESTER MENTAL HEALTH CENTER

STAFF SENIOR PSYCHIATRIST FOR ADULT OUTPATIENT CLINIC PSYCHIATRIST II

SALARY: $25,407.20 - $28,441.00

QUALIFICATIONS: Full Massachusetts License
3 yrs. Psychiatric Residency Training
2 yrs. Post Residency Experience

Dorchester Mental Health Center is a constituent unit of the Boston State Hospital Area Mental Health Program and serves the communities of North Dorchester, Mattapan and Neponset. There is a vacancy for a Staff Senior Psychiatrist for the Adult Outpatient Clinic.

Major responsibilities include supervision and training of multi-disciplinary staff and students and direct clinical services to patients in the Dorchester-Mattapan community. Candidates with administrative abilities will have an opportunity to shape the form of future services.

Applications and curriculum vitaes should be submitted to:

M.H. Nelson, M.D.
Superintendent/Area Program Director
Boston State Hospital
591 Morton Street
Dorchester, Mass. 02124

CHALLENGING OPPORTUNITIES FOR PSYCHIATRISTS

Salary: $28,877 - $38,375
(dependent on qualifications)

Immediate opening for psychiatrists seeking a challenge in developing and implementing a comprehensive, interdisciplinary treatment program for a modern, community-oriented psychiatric center. Elmira Psychiatric Center is an innovative model for the type of client-centered mental health facility which serves as the hub of an active, well-coordinated system of psychiatric services. With satellite programs in adjacent Steuben and Schuyler Counties, the Center strives to meet the needs of nearly 250,000 population at risk. We are presently expanding our program to include inpatient and extended day treatment for children and geriatric clients.

Elmira is located in the beautiful Finger Lakes Region of Western New York, an area offering a year-round variety of sports and recreational activities. Ten colleges, including Cornell University, are within commuting distance. Elmira and its neighboring communities take pride in their good schools, excellent shopping areas, and pleasant pastoral surroundings. Syracuse and Rochester are located approximately two hours away.

We invite your participation in this institution. For more information please write to Director

Elmira Psychiatric Center
P. O. Box 1011
Elmira, NY 14902

ADDICTION RESEARCH FOUNDATION

TORONTO/ONTARIO

The Department of Social and Epidemiological Studies has an opening for a researcher with Social Science background. Applicants should have a Ph.D. in Sociology, knowledge of epidemiological methods in the study of social problems and psychiatric disorders and publications in the field of alcohol and drug dependence or a related area.

Applications with curriculum vitae attached are to be directed to:

Dr. W. Schmidt,
Associate Director of Research,
Addiction Research Foundation,
33 Russell Street,
Toronto, Ontario,
Canada.
M5S 2S1

Milwaukee Psychiatric Hospital — Intensive, dynamic psychotherapy for adults and adolescents, individually-planned activity therapy.

Adolescent Therapy Unit — Designed for the problems of today's emotionally disturbed youth. Patients attend accredited Kradwell High School on the grounds . . . excellent teaching staff . . . credits are transferable.

Dewey Center — Acute detoxification and inpatient treatment for persons with dependency on alcohol and other drugs, daily schedules, broad supportive services.

Milwaukee Sanitarium — Custodial services for persons with chronic emotional and geriatric illnesses.

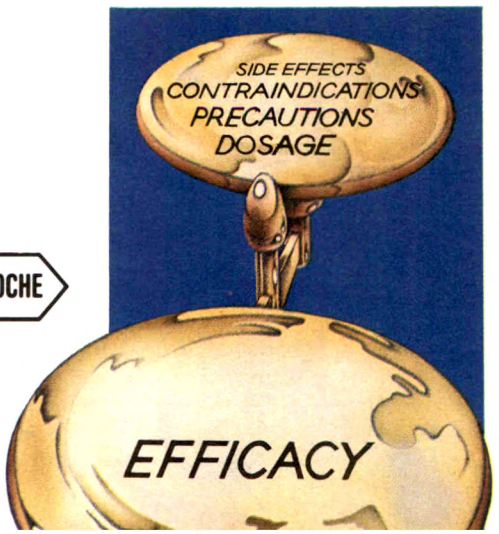
LIBRIUM®
(chlordiazepoxide HCl)
5 mg, 10 mg, 25 mg capsules

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

ROCHE
Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

SAFETY. IT'S A QUESTION OF BALANCE.

In choosing a tranquilizer for the patient whose excessive anxiety is disrupting psychotherapy there are a number of things to consider. One is effectiveness. A second is safety.



The first is more easily established. The second may be ascertained by comparison. In other words, with safety there is the question of balancing a drug's potential benefits against any potential risks.

When the antianxiety agent you are considering is Librium, you should know that it has a wide margin of safety.

The most common side effects of Librium are dose-related and thus largely avoidable. There appears to be a low incidence of drug dependence and tolerance. Librium rarely has any adverse effects on the cardiovascular or respiratory systems, and there are relatively few cases of known toxicity attributable to Librium.

You already know that Librium is effective. But you should also know that Librium, used in proper dosage, rarely interferes with mental acuity and thus is unlikely to interfere with the psychotherapeutic process. In addition, Librium is used concomitantly with many primary medications.

Librium. All in all, a very good balance.

The B24 III

UL LISTED

...a new generation of electroconvulsive therapy instrumentation from Medcraft.

Designed with patient and operator safety in mind, this new series of instrumentation meets the rigorous requirements for listing by Underwriters Laboratories — UL 544, Standards for Medical and Dental Equipment. The B24 III provides the physician with the ultimate in precision dosage levels. Consistancy of desired output level is assured with the following features:

- Line Voltage Compensation — allows compensation for fluctuations in incoming line voltages.
- Pre-programmed Voltage Selection — choice of eleven voltage levels from 70 volts to 170 volts.
- Automatic Treatment Timing — adjustable from 0.1 second to 1.0 second with or without Glissando.
- Current Output Indicators — visual assurance of current flow during treatment.

Exclusive Patient Test Module allows a complete systems integrity check of instrumentation prior to treatment. Clinical accuracy and dependability are assured by the use of 100% solid state circuitry. Double shielded transformer provides an additional margin of treatment safety. 'STELAZINE' PROVIDES EFFECTIVE CONTROL OF HALLUCINATIONS, DELUSIONS, ANXIETY AND OTHER PSYCHOTIC SYMPTOMS.
BECAUSE IT APPEARS TO HAVE AN ACTIVATING EFFECT, 'STELAZINE' IS ESPECIALLY USEFUL IN WITHDRAWN, APATHETIC OR DETACHED PATIENTS.

- CONTROLS PSYCHOTIC SYMPTOMS
- SELDOM CAUSES EXCESSIVE SEDATION
- CONVENIENT B.I.D. DOSAGE

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

INDICATIONS

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

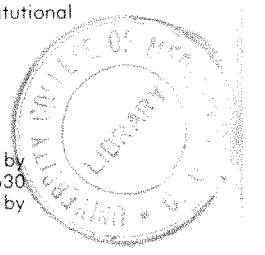
Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.



Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F Co.) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

HELPS WITHDRAWN PATIENTS BECOME MORE RESPONSIVE.

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

80pp. Paperbound

Single copy, $4.00; 10–49 copies; $3.80 each; 50 or more copies, $3.20 each.

SPECIAL OFFER: One copy of this book (regular price, $4.00) and one copy of **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (regular price, $6.50) for $8.50.

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations. fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Wash., D.C. 20009; there will usually be a charge for granting this permission.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHORS' CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

Vulnerability, Coping, and Growth: From Infancy to Adolescence

Lois Barclay Murphy and Alice E. Moriarty

"Very few people have the depth of understanding that Dr. Murphy has of how human beings develop their capacities to deal with life. I strongly urge any serious student of the development of children to buy and read this book."—Burton L. White

"Murphy's study of coping under stress reveals resiliency and later vulnerability in the context of the individual child's resources and the total environment in which the child is growing up. A magnificent book."—Roy R. Grinker, Sr. $20.00

A New Language for Psychoanalysis

Roy Schafer

A provocative and brilliant book offering a radical reconceptualization of Freudian metapsychology. Schafer proposes a new language for psychoanalysis, freed from the ambiguities and biases of mechanistic theory. He presents a philosophically oriented view of the person as agent, one who does things for reasons and creates his or her own experiences. $20.00

Psychiatry and the Humanities

Volume 1

edited by Joseph Smith, M.D.

The first in a series of volumes applying the insights and methodologies of psychoanalysis to the humanities. In this book, six humanists and five psychoanalysts cover a wide range of topics including art, literature, philosophy, language, mysticism, ethics, truth, healing, and creativity. $12.50

Register Now for

APA Self-Assessment Program

by May 31, 1976

The APA announces availability of the third Psychiatric Knowledge and Skills Self-Assessment Program. Program registration will be accepted through May 31, 1976; program materials will be mailed to registrants on June 15, 1976; answer materials should be returned for central scoring by September 10, 1976; and performance data will be mailed on November 15th.

PKSAP-III addresses many areas of daily practice, cognitive and clinical, to stimulate individual learning and motivate each participant to discuss new developments and emerging issues with colleagues. Absolute confidentiality will be maintained in regard to individual results, which will be reported directly and only to the participant.

A Bulletin of Information, an indepth description of the Program, will be mailed to each APA member. However, you may register by completing the form below and submitting it with the appropriate fee to Educational Testing Service, Princeton, New Jersey 08540.

PKSAP-III REGISTRATION FORM—1976

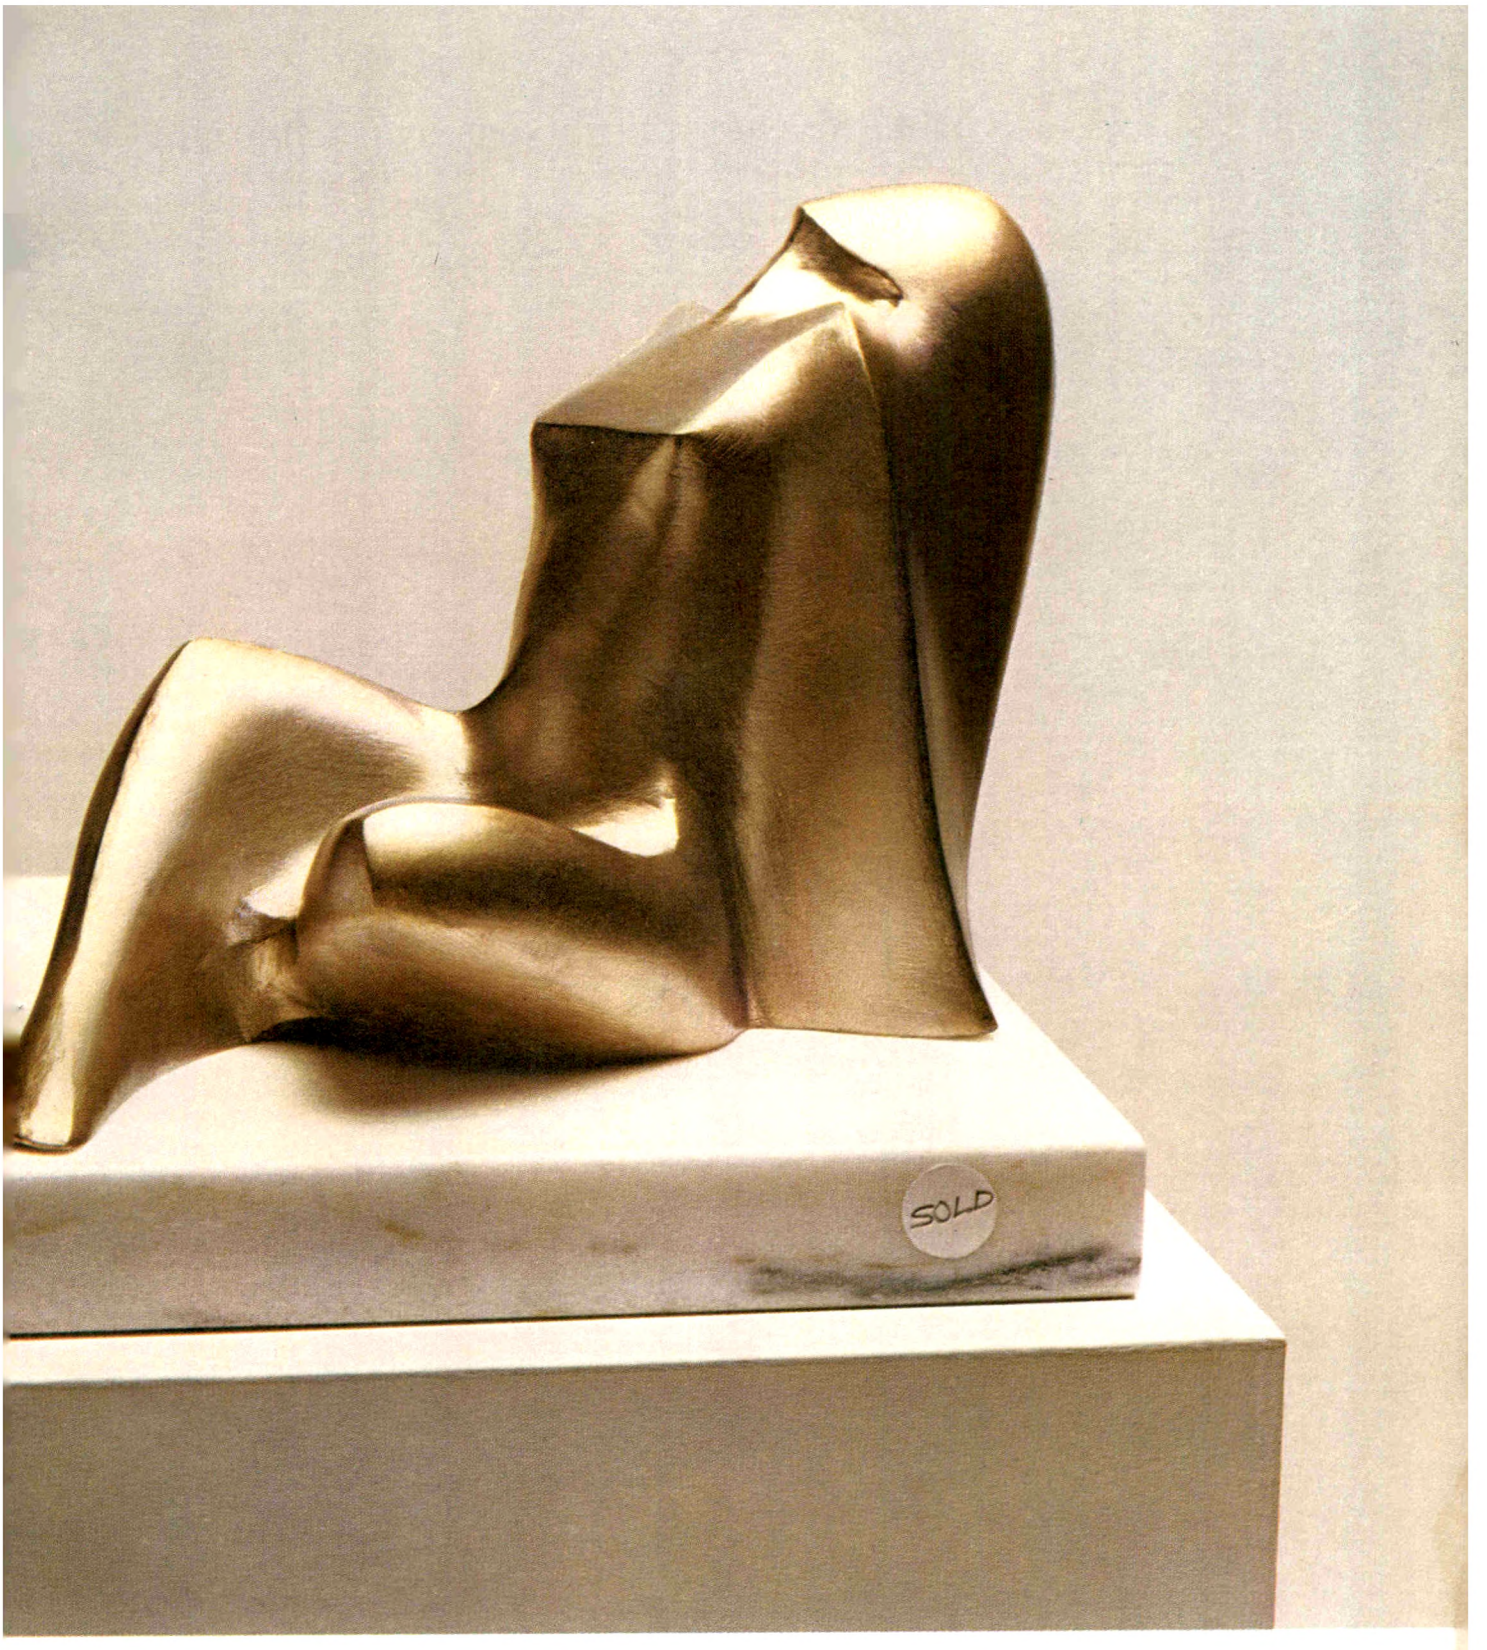
Released from symptoms of psychotic depression...

Productive again.



By helping to reduce the frequency and intensity of psychotic symptoms, Navane (thiothixene) often permits resumption of more normal, more productive living.

The antipsychotic effectiveness of Navane—with relatively little drowsiness—helps patients remain more active, more alert, better able to meet the ordinary demands of life.

Cardiovascular side effects such as hypotension and nonspecific EKG changes are relatively rare with Navane (thiothixene). Extrapyramidal symptoms have been reported, but are usually controlled by reduction in dosage and/or administration of antiparkinson drugs.

Once you've controlled acute psychosis or psychotic depression, some patients can be maintained on a simple once-a-day dose. This once-a-day regimen can reduce the risk of missed doses with no loss of efficacy.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

Navane®

(thiothixene) (thiothixene hydrochloride)

Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg/Concentrate 5 mg/ml

Once-a-day–to help control symptoms of psychosis

For prescribing information, including adverse reactions and contraindications please see following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules 1 mg, 2 mg, 5 mg, 10 mg, 20 mg (thiothixene hydrochloride) Concentrate: 5 mg/ml, Intramuscular: 2 mg/ml

Actions. Navane is a psychotropic agent of the thioxanthene series. Navane possesses certain chemical and pharmacological similarities to the piperazine phenothiazines and differences from the aliphatic group of phenothiazines. Navane's mode of action has not been clearly established.

Indications. Navane is effective in the management of manifestations of psychotic disorders.

Contraindications. Navane is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*—Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children—The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration—As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane. Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudoparkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leucocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution—For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate—In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor elevating action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Picrotoxin or pentylenetetrazol should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg. of thiothixene in bottles of 100 and 1,000. Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100 and 500.

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

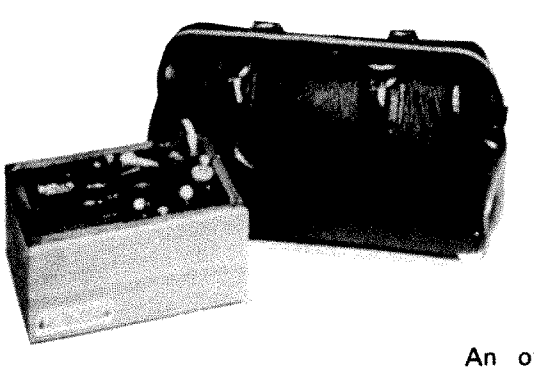
ROERIG Pfizer
A division of Pfizer Pharmaceuticals

MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

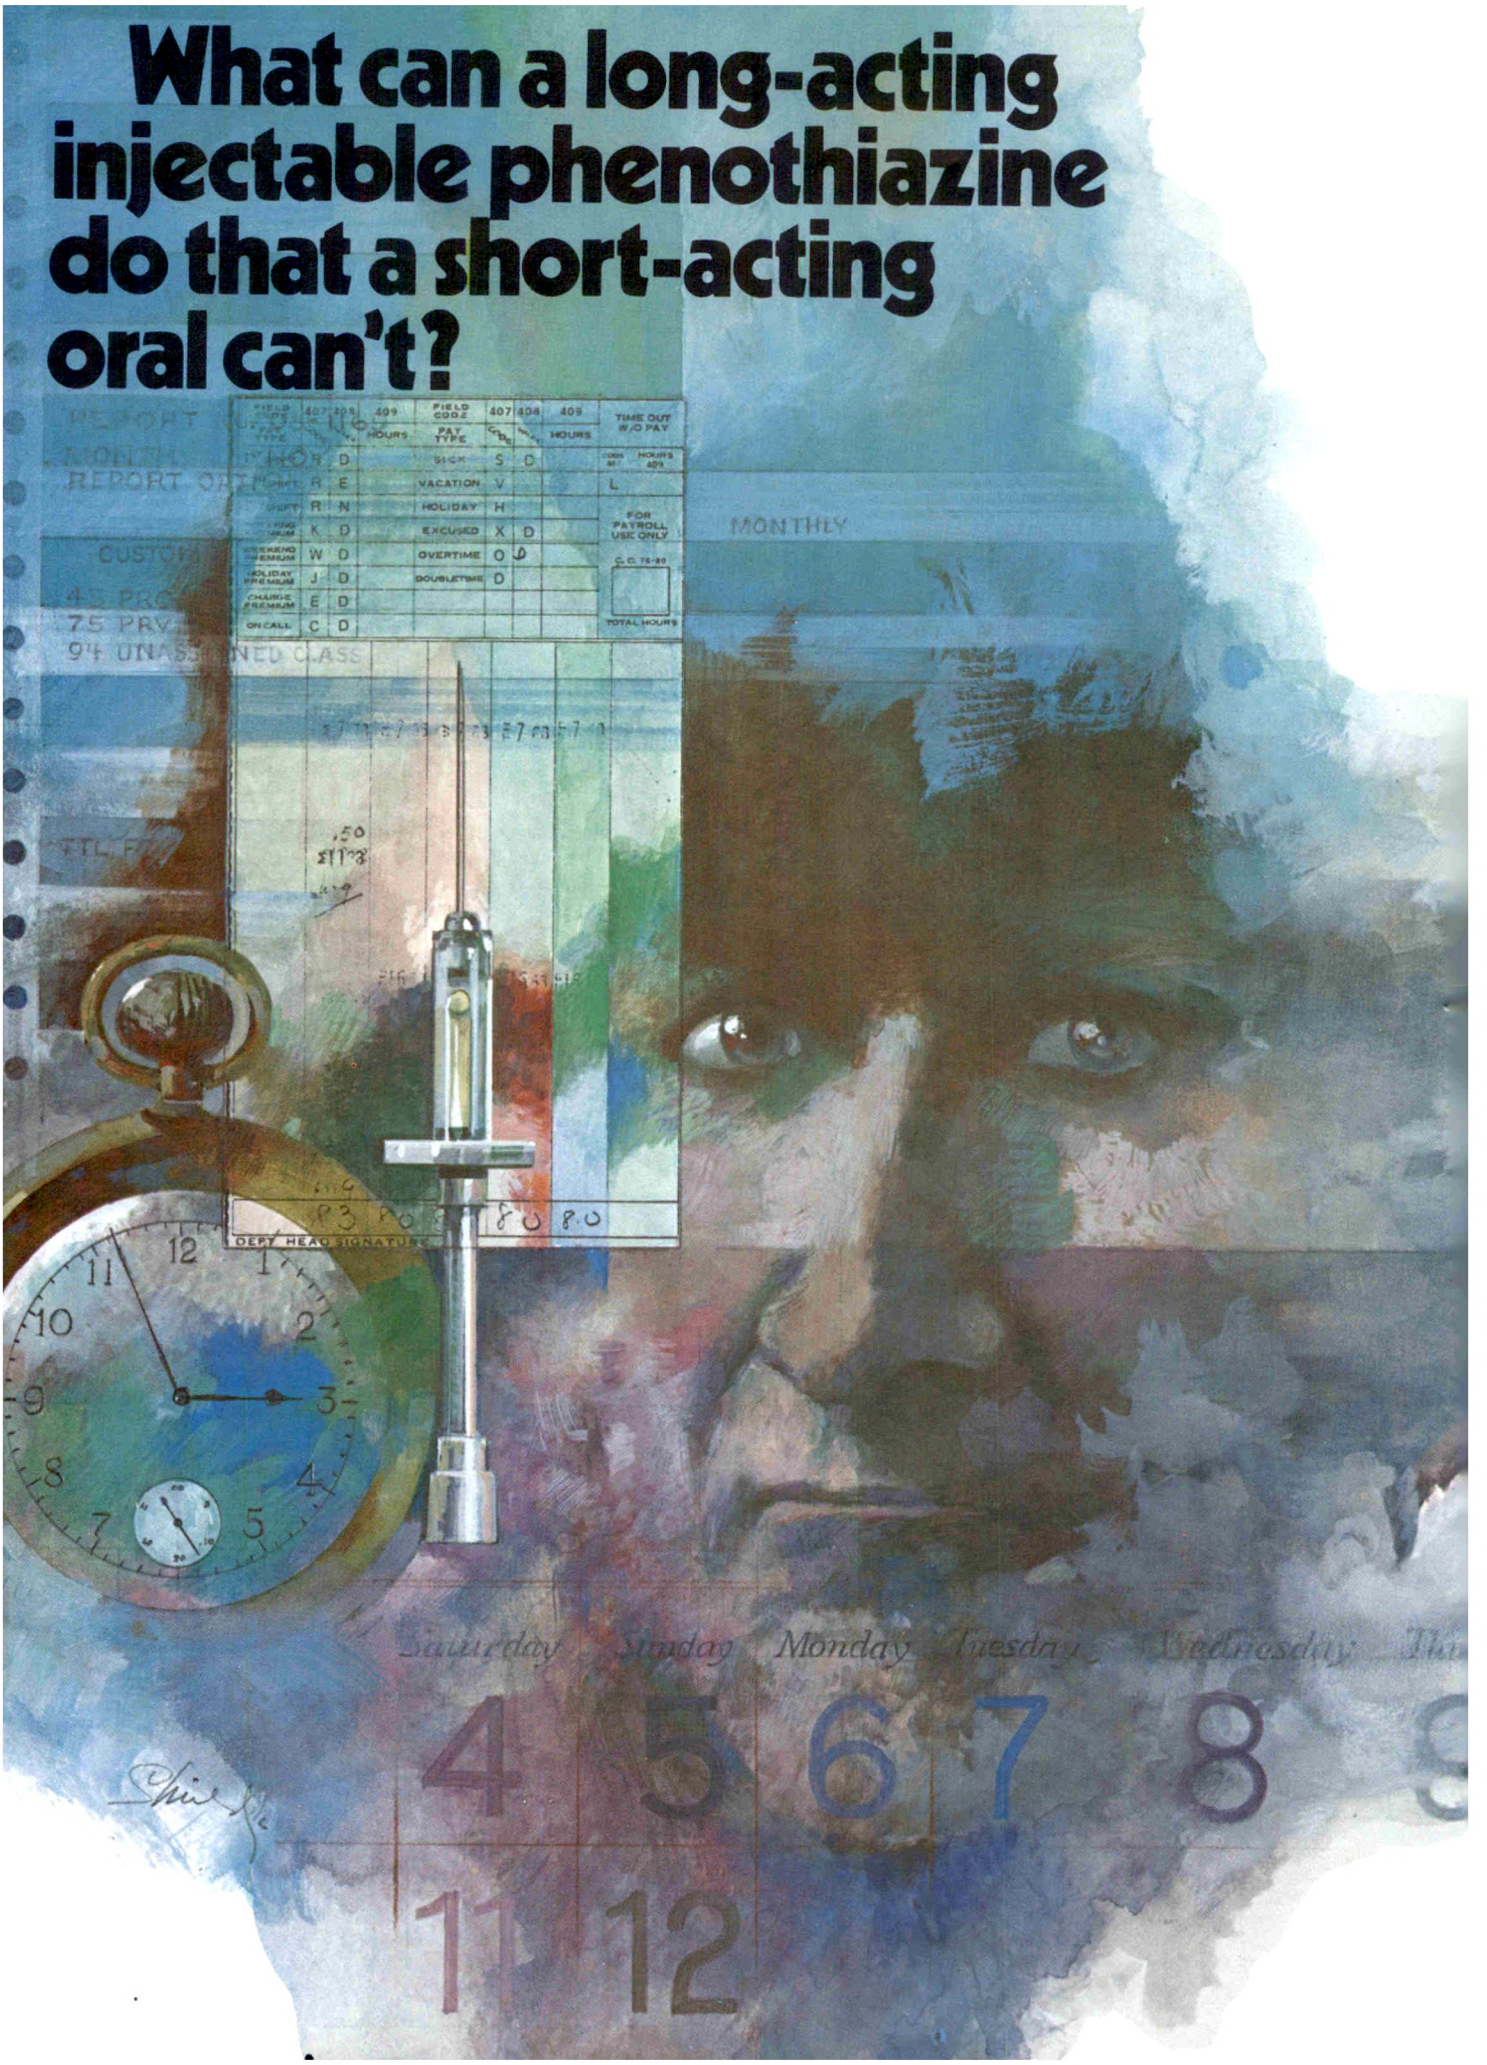
Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.



Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

See us at Booth F5 at the Annual Meeting

What can a long-acting injectable phenothiazine do that a short-acting oral can't?

It can save time, it can save money, and it can even save people – by reducing readmissions.

Time Prolixin Decanoate (Fluphenazine Decanoate Injection), with duration of action that may last up to 4 weeks or longer in patients on maintenance therapy, can effect important savings in nursing time.

Approximate Staff Time Required to Medicate 18 Schizophrenic Patients*

8 a.m. ¾ hr. 1 p.m. ¾ hr. 5 p.m. ¾ hr.	1 injection every 28 days for most patients
= 2¼ hours nursing time	4 minutes required for each injection
2¼ hrs. x 28 days = 63 hours of nursing time every 28 days	= 1 hr., 10 minutes nursing time in 28 days
NURSING TIME SAVED IN 28 DAYS	61 hours and 50 minutes or more than 7½ eight-hour working days

*Adapted from Platt R. Br J Social Psychiatry 2: 187-191, 1968.

Money Martin and Townend[1], who found from their study of Prolixin Decanoate that 15 of 39 patients could be maintained on 25 mg. every 4 weeks, also note that on this basis " a year's maintenance on chlorpromazine represents the order of 110 grams of phenothiazine as opposed to 0.33 gram of fluphenazine." Translating this into dollars shows the following potential hospital savings on the basis of patient population:

Agent and amount/year	Form	Cost/patient/year	Cost/500 patients/year
Chlorpromazine (SKF brand) 110 grams	8 oz. concentrate 100 mg./ml.†	$48.75*	$24,375
Prolixin Decanoate .33 grams	5 ml. vials 25 mg./ml.	23.17**	11,585
SAVINGS		$25.58 patient, year	$12,790 500 pts/yr.

* Calculated from prices published in 1975 Red Book
** Calculated from Squibb 1975 price catalogue
† With tablets, the annual cost is even greater.

People The controlled drug delivery system of Prolixin Decanoate helps get schizophrenic patients out of the hospital and helps them stay out. It promotes continuity of therapy—reducing outpatient drug defaulting from approximately 50% with oral medications according to one report[2] to about 16% according to another report[3].

It reduces the number and length of rehospitalizations. In one study of 103 patients maintained on injections of long-acting fluphenazines, total hospital readmissions for a year were cut from 191 to 50 and inpatient time from 8,713 days to 1,335 days[4].

It facilitates return to a productive life. A 12-month followup of 103 discharged patients revealed 77% in full-time employment or household duties and only 23% unemployed[4].

PROLIXIN DECANOATE®

(Fluphenazine Decanoate Injection)

may control schizophrenic symptoms for up to 4 weeks or longer in patients on maintenance therapy.

For product brief summary see following page.

H425-001R

PROLIXIN DECANOATE®

(Fluphenazine Decanoate Injection)

may control schizophrenic symptoms for up to 4 weeks or longer in patients on maintenance therapy.

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per ml. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety and efficacy in children have not been established because of inadequate experience in use in children.

Usage in Pregnancy: Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administering this drug to pregnant patients.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with a history of convulsive disorders since grand mal convulsions have occurred, and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams; reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 ml. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 ml. vials.

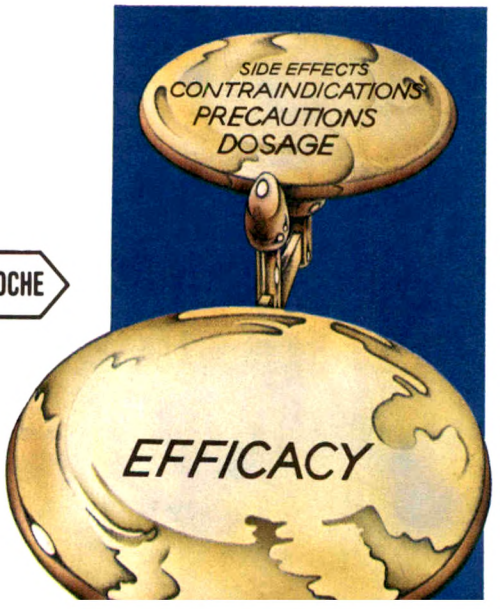
LIBRIUM®
(chlordiazepoxide HCl)
5 mg, 10 mg, 25 mg capsules

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.
Contraindications: Patients with known hypersensitivity to the drug.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.
Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.
Supplied: Librium® Capsules containing 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 mg, 10 mg or 25 mg chlordiazepoxide.

ROCHE
Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

SAFETY. IT'S A QUESTION OF BALANCE.

In choosing a tranquilizer for the patient whose excessive anxiety is disrupting psychotherapy there are a number of things to consider. One is effectiveness. A second is safety.



The first is more easily established. The second may be ascertained by comparison. In other words, with safety there is the question of balancing a drug's potential benefits against any potential risks.

When the antianxiety agent you are considering is Librium, you should know that it has a wide margin of safety.

The most common side effects of Librium are dose-related and thus largely avoidable. There appears to be a low incidence of drug dependence and tolerance. Librium rarely has any adverse effects on the cardiovascular or respiratory systems, and there are relatively few cases of known toxicity attributable to Librium.

You already know that Librium is effective. But you should also know that Librium, used in proper dosage, rarely interferes with mental acuity and thus is unlikely to interfere with the psychotherapeutic process. In addition, Librium is used concomitantly with many primary medications.

Librium. All in all, a very good balance.

Tested by time and experience i

1962

"...a considerable decrease of hyperactivity...."[1]
Knobel, 1962

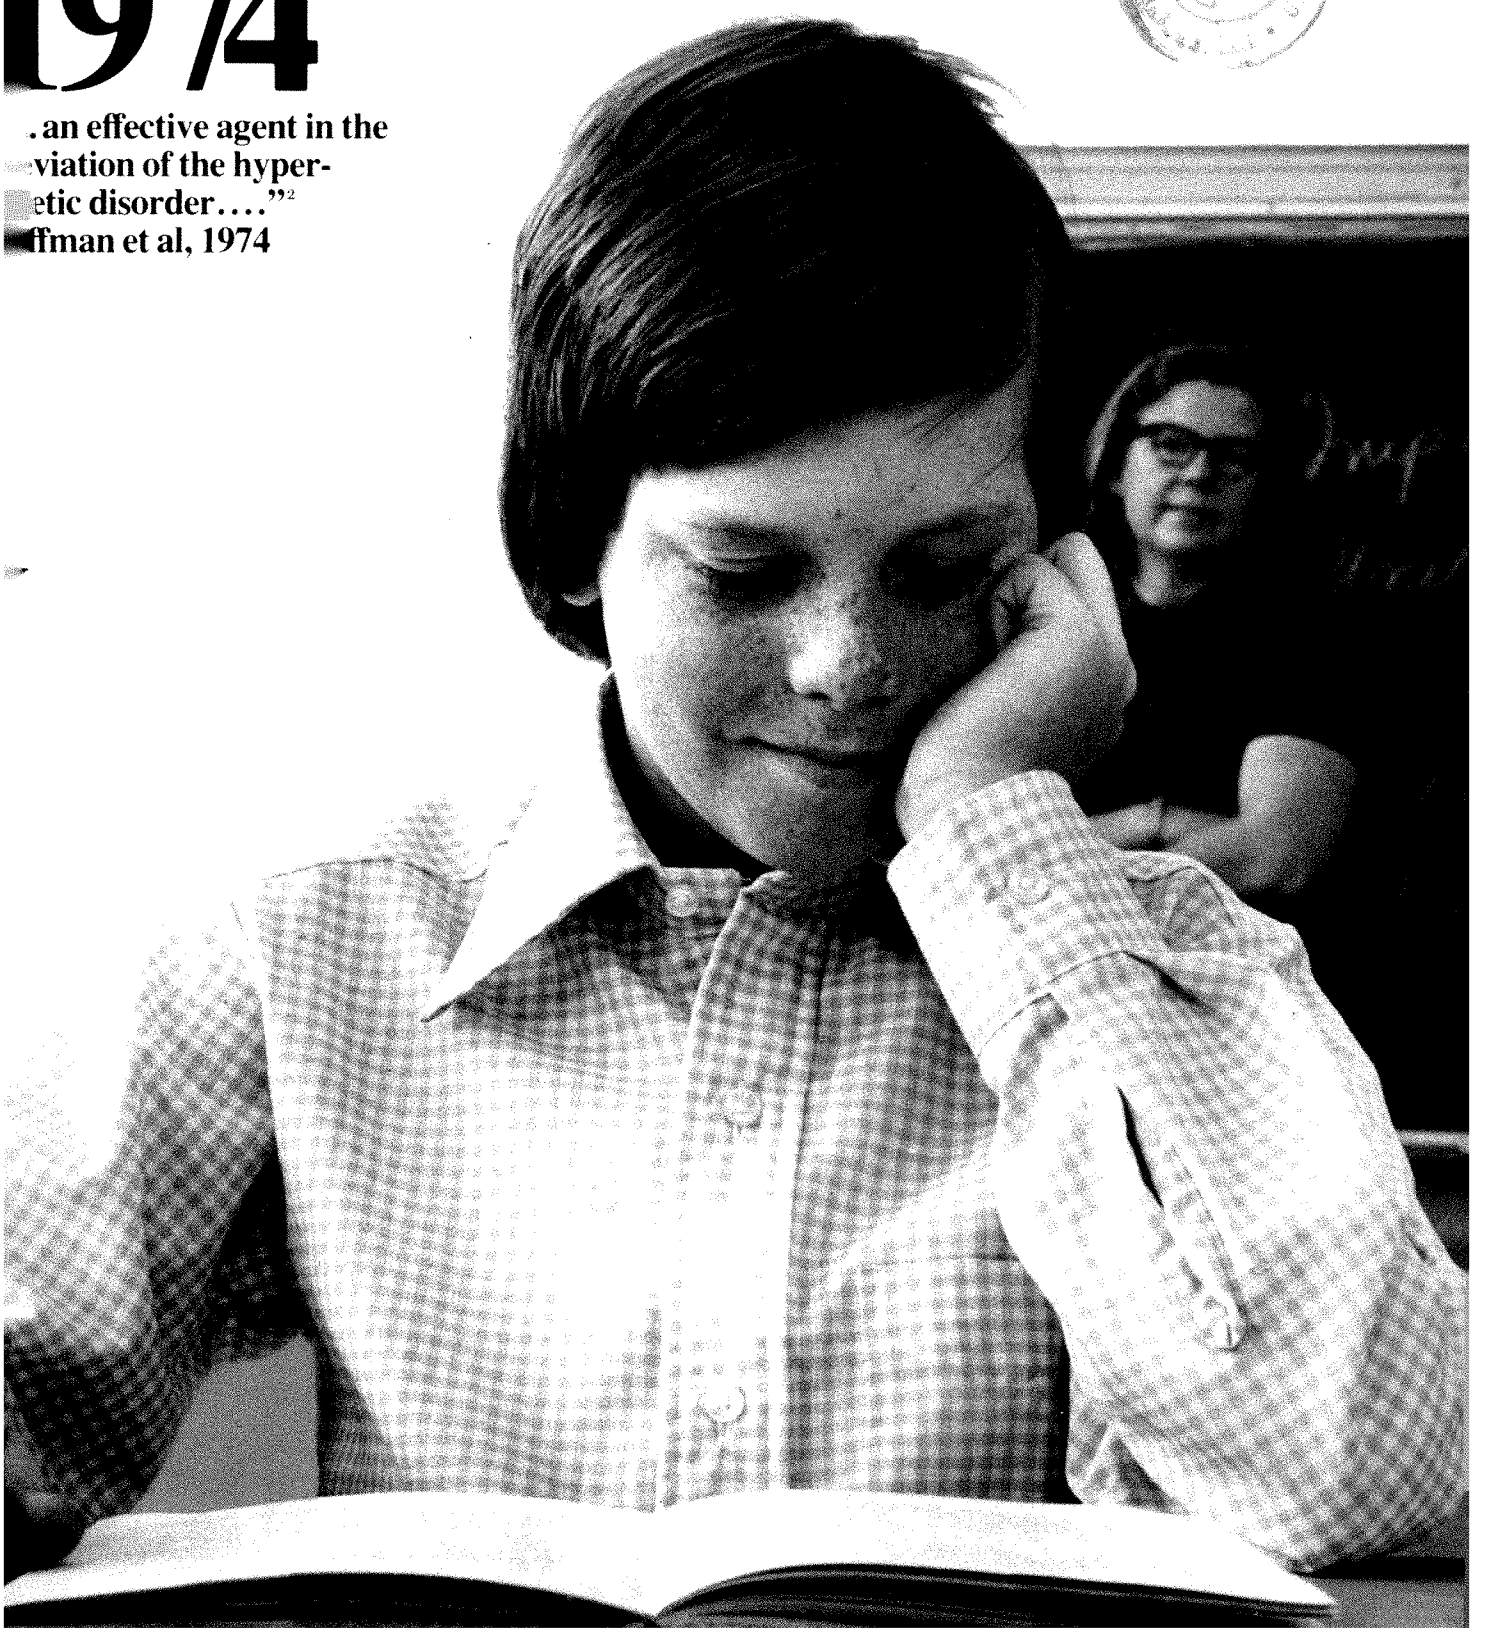
Over a decade of controlled studies and clinical experience has shown the effectiveness of Ritalin in reducing the hyperactivity,[1-3] distractibility,[1,4,5] and disorganized behavior[1-8] in the MBD child.

By lessening the effects of motor and attentional disorders, Ritalin can help the MBD child to better focus his attention on meaningful stimuli and thus can often improve cognition and promote learning.[6,9]

And side effects – insomnia ar appetite loss – with Ritalin have occurred less frequently than with dextroamphetamine.[10,11]

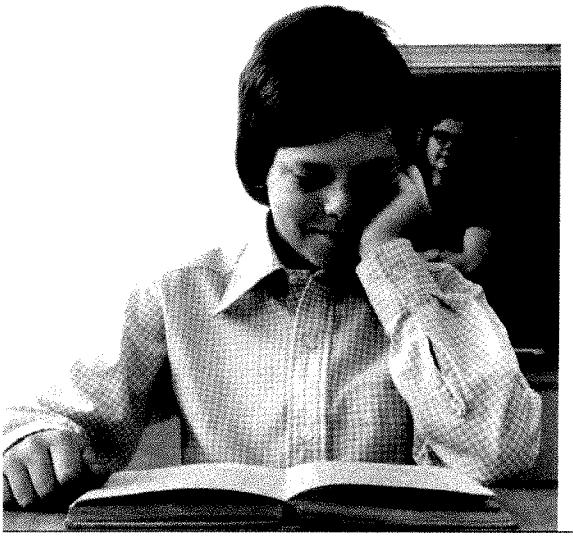
Indeed, Ritalin is currently a drug of choice in many MBD situations,[10,12] and can prove to be an important element in many complete remedial programs for MBD.

Therapy with Ritalin should b undertaken only after a medical diagnosis of MBD has been made. Drug treatment is not indicated for all children with MBD.



Dosage should be periodically interrupted. Often, these interruptions reveal some "stabilization" in the child's behavior even without medication, permitting a reduction in dosage and eventual discontinuance of drug therapy.

Ritalin®
(methylphenidate)
Only when medication is indicated



he treatment of MBD

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronic ly abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

Morita Psychotherapy

David K. Reynolds

Morita psychotherapy, a Buddhist-based Japanese therapy for the treatment of neuroses, is currently being practiced in its original in-patient form in several hospitals in Japan. For the first time, we have in this book, a full-length description in English of a fundamentally Eastern approach to man's neurotic tendencies, treatment, and cure.

252 pages, $10.95

Suicide: Inside and Out

David K. Reynolds and Norman L. Faberow

"Mental hospitals have rules and regulations —but those rules and regulations don't keep people alive. Only other people can keep people alive."—*Dr. David K. Reynolds*

For this unique examination of the causes of suicide among psychiatric patients, Reynolds adopted the identity of a severly depressed young war veteran, received treatment in a psychiatric hospital, and wrote his account of the interaction between his social world and his psychological functioning.

240 pages, $10.95

The Great Universe of Kota

Stress, Change and Mental Disorder in an Indian Village

G. M. Carstairs and R. L. Kapur

Much is known about the incidence of neuroses and stress disorders in Western societies, but much less about their occurrences in the Third World. This book describes an inquiry—in many respects unprecedented—in which modern methods of social research have been employed to elicit, in their own language, how three groups of Indian villagers perceive symptoms of mental disturbance in themselves and in their neighbors.

4th edition

A Psychiatric Glossary

Edited by a subcommittee of the AMERICAN PSYCHIATRIC ASSOCIATION Committee on Public Information.

The new Fourth Edition marks a striking expansion of definitions: 400 terms have been added and many of the terms appearing in earlier editions have received revised explanations. In addition to the GLOSSARY's continuing value to lawyers, teachers, journalists, social workers, and others, the new edition will be useful to medical students and first year residents in psychiatry.

Some major changes in the Fourth Edition:

- Expansion from 102 to 156 pages to accommodate 400 new terms
- New tables of terms in seven areas of contemporary concern
  - Drugs Used in Psychiatry
  - Legal Terms
  - Neurologic Deficits
  - Psychological Tests
  - Research Terms
  - Schools of Psychiatry
  - Sleep Disorders
- A comprehensive set of terms used in behavior therapy is included for the first time.

Paperback edition—$3.00 each, (See coupon for bulk discounts), may be ordered from the AMERICAN PSYCHIATRIC ASSOCIATION, Publications Sales, 1700 18th St. N.W., Washington, D.C. 20009.

Hardback edition—$7.95 may be ordered from Basic Books, Inc., 10 East 53rd Street, New York, New York 10022.

Everybody knows somebody who's been helped.

The United Way is reaching out. It goes into every neighborhood. To every age group. Across every income level.
To help. In a thousand ways.
A neighbor. A relative. Maybe someone down the street who's out of work. Or sick. Or in trouble.
Chances are the United Way helps someone you know. Maybe someday it'll be helping you.

Thanks to you it works...

No default insurance

Tofranil-**PM**®
imipramine **pamoate**

Geigy

In depression

Daily Dosage Chart

1 h.s.

A major reason for drug defaulting is multiple daily dosage schedules.

Ayd* reports that 70 percent of patients default on a q.i.d. regimen; 60 percent on t.i.d.; 30 percent on b.i.d., and only 7 percent on a single daily dose.

A single daily capsule that provides a full day's medication would logically assure better therapeutic results.

Because one capsule lasts from bedtime to bedtime, Tofranil-**PM**® may markedly reduce the probability of missed doses.

After therapy is initiated with the 75-mg. capsule, the 150-mg. capsule is the dose level at which optimum response is usually obtained.

Please review the prescribing information summarized on the back of this page.

*Ayd, F.J., Jr. (Ed.): Int. Drug Ther. Newslett. 7(9/10):35-50 (Nov./Dec.) 1972.

Tofranil-**PM**®
imipramine **pamoate**

One capsule
lasts from bedtime
to bedtime.

Initial Dose

For Maintenance Therapy

Starting Dose	Usual Optimum Response Dose	A Full Range to Choose From*			
					
75 mg.	150 mg.	150 mg.	125 mg.	100 mg.	75 mg.

*Each capsule contains imipramine pamoate equivalent to 150, 125, 100 or 75 mg. imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;
—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;
—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;
—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;
—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response. If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks.

Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

Basic tools of primitive psychiatry

Mankpo: Sceptres or staffs used by the Heviosso (lightning God) cult in medical ceremonies among the Ewe of Tongo and Fon of Dahomey. *Right,* staff with leopard's head, bared teeth and tongue (Ewe, Togo). *Left,* staff with ram's head—the sacred animal of the Heviosso—in the form of a serpent symbolizing the fire-spitting rainbow God of healing (Fon, Dahomey). From the collection of the Segy Gallery, New York City.

Basic tool of Western psychiatry

Thorazine®
(chlorpromazine, SK&F)

Tablets: 25 and 50 mg of the HCl

- 'Thorazine' controls psychotic symptoms
- Especially useful in agitated, violent or anxious schizophrenic patients
- Unsurpassed clinical experience
- 18 convenient dosage forms and strengths

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

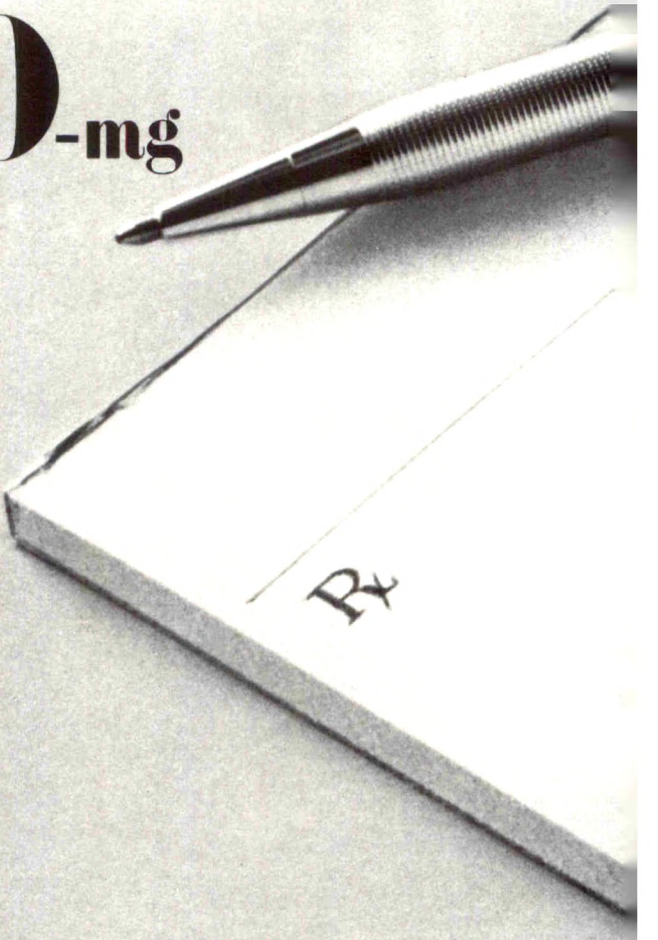
For effective management of schizophrenic symptoms.

for clinically significant depression. . .

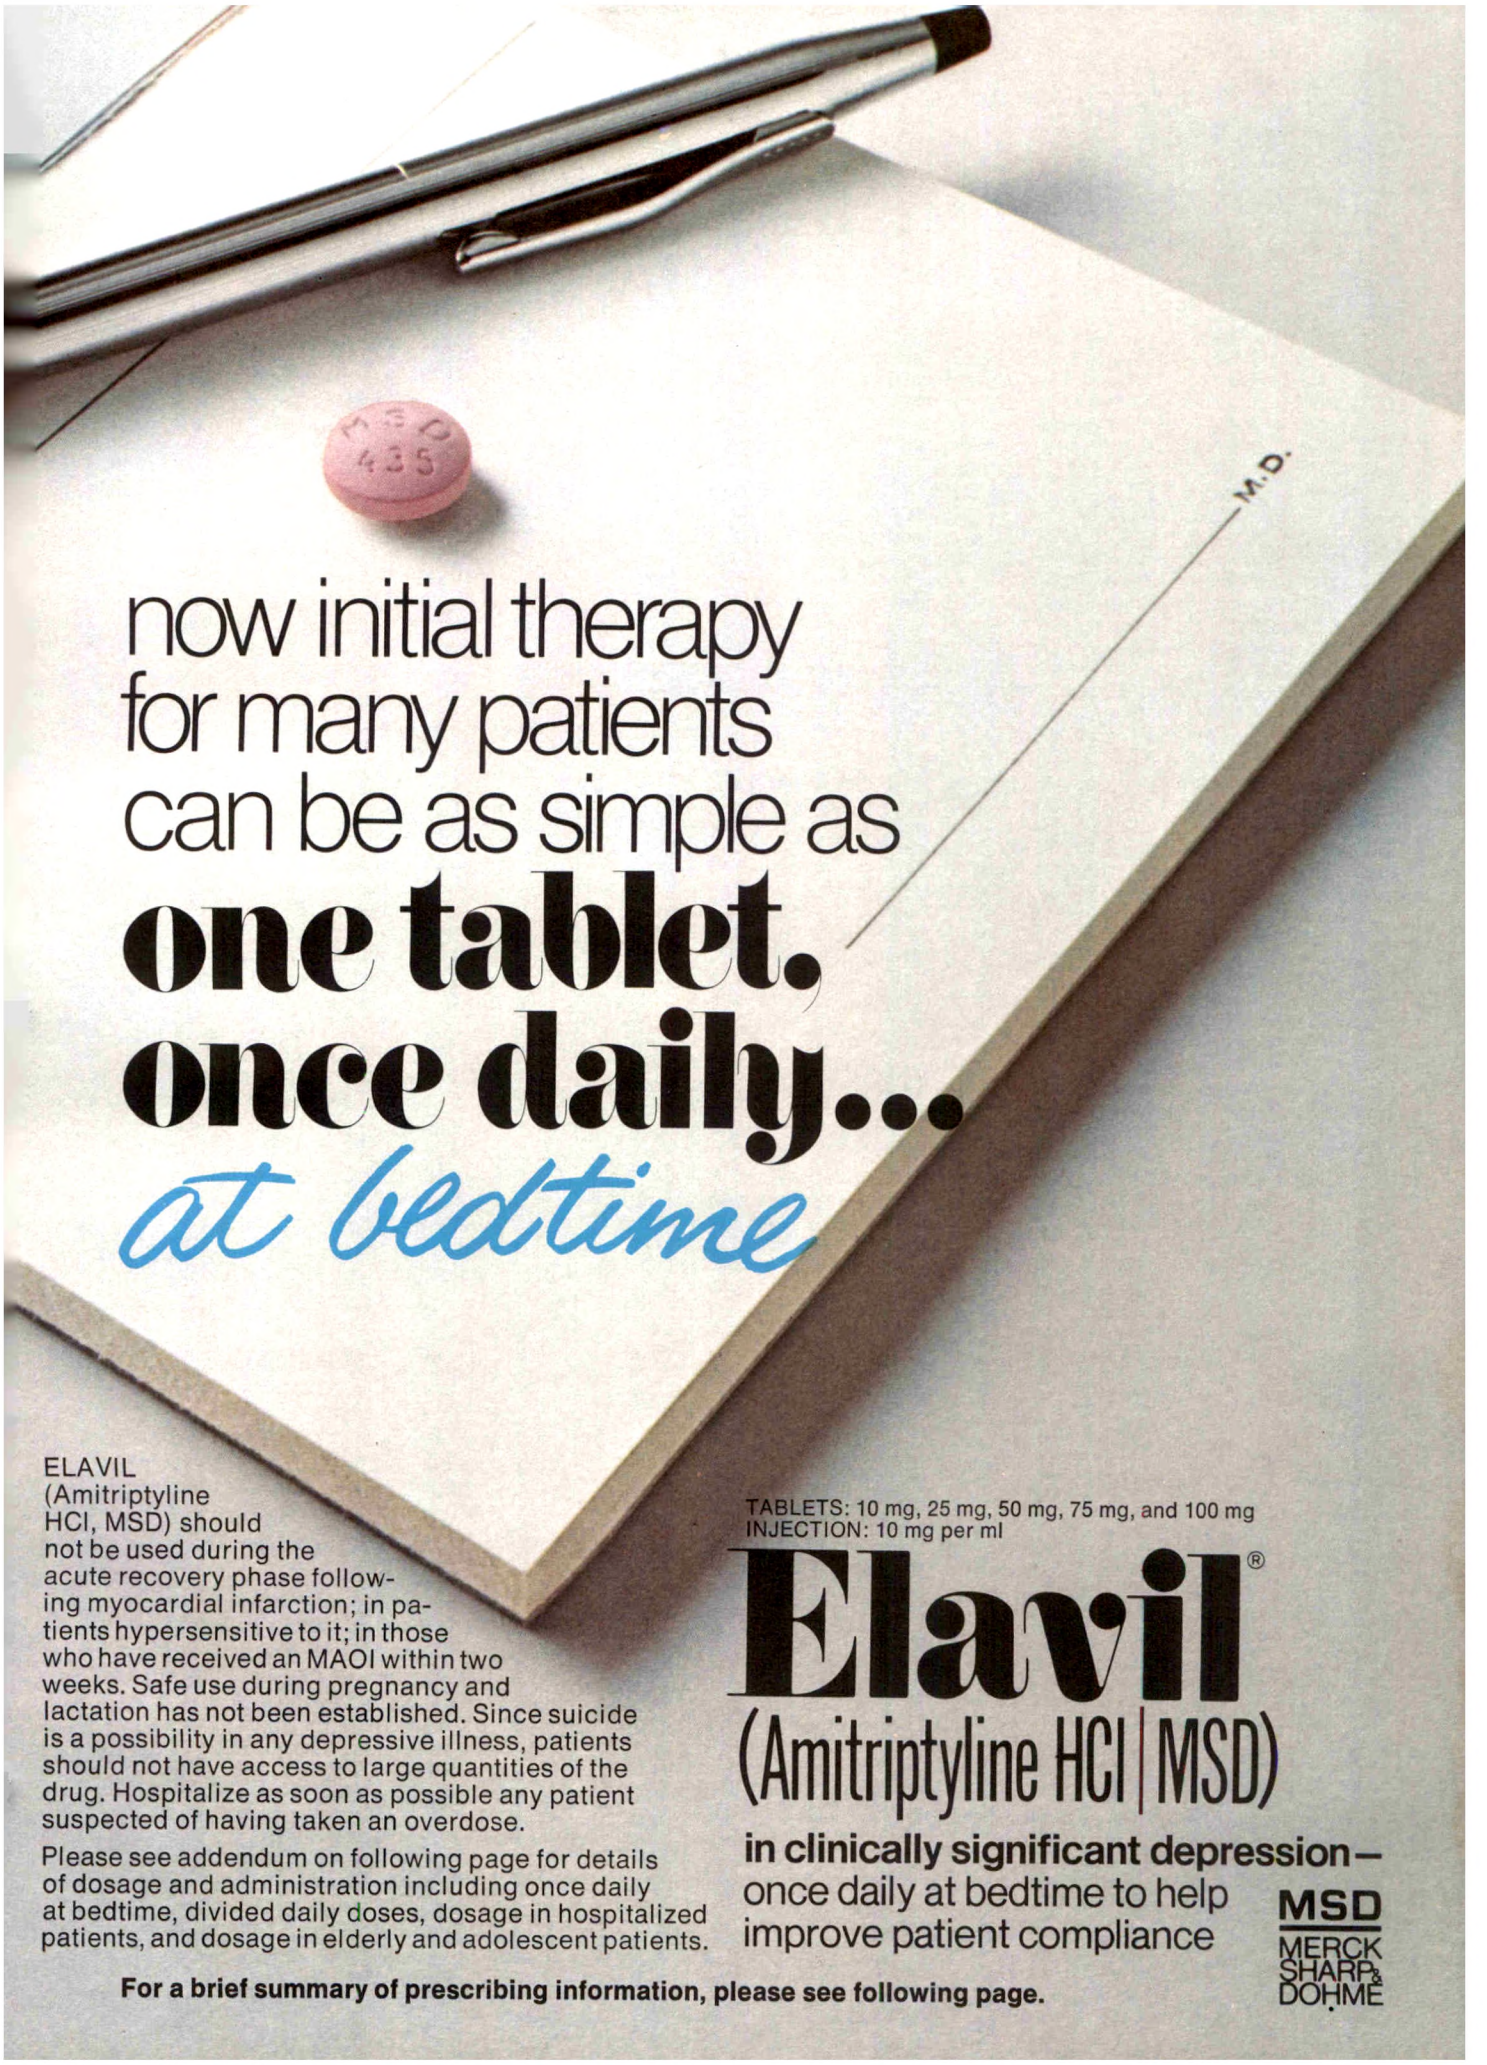
Merck Sharp & Dohme introduces

75- and 100-mg

TABLETS



Elavil®



(Amitriptyline HCl | MSD)

to further simplify once-daily

h.s.

therapy

now initial therapy for many patients can be as simple as **one tablet, once daily...** *at bedtime*

ELAVIL (Amitriptyline HCl, MSD) should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks. Safe use during pregnancy and lactation has not been established. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

Please see addendum on following page for details of dosage and administration including once daily at bedtime, divided daily doses, dosage in hospitalized patients, and dosage in elderly and adolescent patients.

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg
INJECTION: 10 mg per ml

Elavil®
(Amitriptyline HCl | MSD)

in clinically significant depression— once daily at bedtime to help improve patient compliance

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please see following page.

NEW TABLETS

Elavil®

(Amitriptyline HCl | MSD)

75 mg and 100 mg

to further simplify once-daily

h.s.

therapy

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramical symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

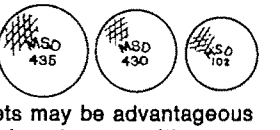
addendum

MSD
MERCK SHARP & DOHME

Elavil®



(Amitriptyline HCl | MSD)

Five tablet strengths for differing patient needs. The variety of dosage strengths available with ELAVIL makes possible great prescribing flexibility.

Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. The simplicity of this regimen helps improve patient compliance. ELAVIL may also be prescribed in divided daily doses.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.

100 mg
75 mg
50 mg

These tablets may be advantageous when initiating therapy with once-daily bedtime dosage in adult outpatients. The usual starting dosage is 75 mg daily. Therapy may be initiated with 50 to 100 mg daily. This may be increased by 25 or 50 mg as necessary in the bedtime dose to a total of 150 mg per day.

These tablets may also be convenient for many hospitalized patients. These patients may need 100 mg a day initially which can be increased gradually to 200 mg a day if necessary. A small number of such patients may need as much as 300 mg a day.

25 mg

This tablet may prove useful when initiating therapy with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime doses.

10 mg

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

Schering

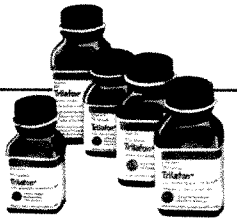
Out of touch

but not beyond reach...

Help restore reality

- low dose, high potency phenothiazine useful for inpatient and outpatient treatment
- helps orient psychiatric patients to their surroundings
- effective with minimal sedation, usually produces little lethargy or drowsiness

Trilafon®
brand of
perphenazine, NF
for management of disturbed behavior in schizophrenic and manic states



Versatile Dosage	
Injection	5 mg/ml, 1 ml ampul
Concentrate	16 mg/5 ml, 120 ml bottle
Tablets	2,4,8,16 mg
REPETABS® Tablets 8 mg brand of repeat-action tablets	

Please see next page for prescribing information.

Trilafon®
brand of
perphenazine, NF

For management of schizophrenic and manic disorders in psychiatric hospitals, mental health clinics, and with outpatient treatment

BENEFITS

TABLETS
for maintenance or control of patients in hospital or home

- generally improve cooperation and communication
- decrease need for custodial care, hasten discharge

CONCENTRATE
for maintenance or control of uncooperative in-hospital patients

- easily mixes with most liquids
- ensures easy, steady, certain administration

INJECTION
for emergency control of uncooperative in-hospital patients

- usually takes effect in 10 minutes
- average duration of effect is 6 hours

TRILAFON® Tablets
brand of perphenazine, NF

REPETABS® Tablets
Concentrate
Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON **Injection** should not be given to patients in coma or severely depressed states.

WARNINGS **Dosage in pregnancy:** Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operating machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenazine should be under medical supervision, particularly if they are receiving high doses. Patients who have had any severe reaction to phenothiazines or to imipramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patients treated with perphenazine, the possibility that they might occur with TRILAFON should be considered: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the visual fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyphagia; photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, but not epinephrine, because epinephrine's action is blocked and partly reversed by perphenazine. Severe, acute hypotension has occurred with the use of phenothiazines and is of particular concern in patients with mitral insufficiency or pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic reaction to perphenazine; treatment with perphenazine should be stopped if this occurs.

The antiemetic effect of perphenazine can obscure signs of toxicity due to overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor or intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefore, contact of hands or clothing by those handling perphenazine solutions should be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-system-depressant actions of opiates, antihistamines, barbiturates, and alcohol, less than the usual dosage of these agents is required when they are administered concomitantly with TRILAFON. Patients should be cautioned that their response to alcohol may be increased while they are being treated with TRILAFON.

Phenothiazines also potentiate the effects of atropine, heat, and phosphorus insecticides, and should be used with caution in persons exposed to these agents.

ADVERSE REACTIONS *Extrapyramidal reactions:* dystonia including protrusion, discoloration, aching and rounding of the tongue; tonic spasm of the masticatory muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric crisis, trismus, torticollis, retrocollis, muscle weakness, and aching and numbness of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; hyperreflexia; and ataxia. The incidence and severity of these reactions usually increase with increased dosage, but have occurred in some patients receiving low dosage. Reduction in dosage or treatment with an antispasmodic agent will usually control extrapyramidal reactions. In some instances, however, these reactions may persist after discontinuation of treatment with perphenazine.

Persistent tardive dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities. There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine, vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON **Injection** have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON (perphenazine) **Injection** is a rare occurrence.

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

MAY BE AN APPROPRIATE CHOICE FOR YOUR NEXT PATIENT WITH CLINICAL DEPRESSION/ANXIETY

See Brief Summary on last page of advertisement for information on adverse reactions, contraindications, warnings and precautions.

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and
ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

Proved efficacy in the treatment of clinical depression/anxiety

In the five years since its introduction, Sinequan (doxepin HCl) has objectively demonstrated its value in the treatment of clinical depression/anxiety. Clinical studies have shown Sinequan to be unsurpassed in effectiveness when compared to other tricyclic antidepressants.

In addition, Sinequan may offer certain advantages not generally seen with some other drugs of its class:

Marked antianxiety activity

In addition to its significant antidepressant activity, which is usually seen two to three weeks after initiation of therapy, Sinequan possesses marked antianxiety activity.

In double-blind comparisons between doxepin and amitriptyline,[1-3] the antidepressant effects of both drugs were comparable; however, more notable antianxiety effects were seen with doxepin. Superior antianxiety activity was reported among depressed patients treated in a crisis intervention clinic.[4]

Prompt sedative activity

Of the tricyclic antidepressants, Sinequan has been found to have one of the most prominent sedative effects.[5] This sedative property can be taken advantage of by administering the major portion of the daily dose *h.s.* Since clinically depressed/anxious patients frequently have accompanying sleep disturbances, this may be a valuable benefit.

Generally does not affect the activity of guanethidine at usual clinical doses[6]

"A new tricyclic antidepressant, doxepin, was evaluated for its ability to block the amine uptake mechanisms of the peripheral adrenergic neuron and blood platelet in man. At low doses, there was no evidence of inhibition of the amine pump." At clinical dosages up to 150 mg. per day, Sinequan can be given to man concomitantly with guanethidine and related compounds without blocking the antihypertensive effect.[6]

Cardiovascular side effects reported infrequently

In a series of double-blind comparative studies, 1706 doxepin-treated patients were evaluated for side effects. Incidence of tachycardia was associated with only 45 (2.6%) clinically depressed/anxious patients.[3]

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and
ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate
Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.
Warnings. The once-a-day dosage regimen of SINEQUAN in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.
Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.
Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, paresthesias, ataxia, and extrapyramidal symptoms.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, facial edema, photosensitization, pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, and anorexia have been reported. (See anticholinergic effects).

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice and alopecia have been occasionally observed as adverse effects.
Dosage and Administration. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

As an alternative regimen, the total daily dosage, up to 150 mg., may be given on a once-a-day schedule without loss of effectiveness. This dose may be given at bedtime.

Anti-anxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.
Supply. Available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). SINEQUAN (doxepin HCl) 25 mg. and 50 mg. also available in bottles of 5000. SINEQUAN Oral Concentrate (10 mg./ml.) is available in 120 ml. bottles with an accompanying dropper calibrated at 5 mg., 10 mg., 15 mg., 20 mg., and 25 mg. SINEQUAN Oral Concentrate should be diluted with approximately 120 ml. of water or orange juice prior to administration.

FRESH PERSPECTIVES FROM

WILLIAMS & WILKINS

428 E. PRESTON STREET
BALTIMORE, MARYLAND 21202

Clinical Geropsychiatry
by Adrian Verwoerdt, M.D.

Providing mental health services for the aged is rapidly becoming an urgent concern for psychiatrists working within the gerontological specialties.

CLINICAL GEROPSYCHIATRY is an insightful and ultimately indispensable guide to the problems attributed to the aging personality. Working within a medical-psychological framework, Dr. Verwoerdt has based his consideration on the biological, psychological, and social levels of human activity. His presentation of theoretical concepts serves to facilitate a better understanding of the psychopathology of growing old as well as an approach to treatment focusing on the origins of those symptoms associated with aging.

The material is organized into 22 chapters, each covering a separate and distinct facet of aging, supplemented with a list of references and suggestions for further study.

1976/325 pages/$16.95

The Sexual Experience
edited by Benjamin J. Sadock, M.D., Harold I. Kaplan, M.D., Alfred M. Freedman, M.D.

The editors have called on 47 of the most knowledgeable and experienced authorities on sexuality to present this subject in all its richness and contradiction. No perspective has been denied in this unprecedented contribution to the literature of sexuality. In addition to perceptive discussions of sexual development, behavior, and identity, the text includes clinical reviews of the latest research on sex and medicine, marriage, and mental illness. Of special interest are several articles unique in their expanse of detail on such relevant topics as sex and the arts, sex legislation, pornography, and prostitution. A brilliant essay on the women's movement enumerates the effects of the movement on the social and economic circumstances of female life and thus on the changing nature of female sexual behavior.

1976/about 700 pages/117 illustrations, 14 tables/$23.50

Clinical Management of Sexual Disorders
edited by Jon Meyer, M.D.

In preparing this text, Dr. Meyer has met the need for a single volume containing the best of recent thought on remedial therapy for patients with sexual disorders including the determination of significant variables in sexual conditions, and the application of selected treatment techniques.

Each phase of the treatment process is adequately presented from the perspective of one or more well-qualified authorities on their particular subject. The nineteen contributors have provided thorough documentation so that anyone interested in further pursuit of the subject may easily know where to begin the search.

Addressed to no particular specialty, this volume will provide a valuable supplement to the skills of any clinician or practitioner who must regularly confront the problems associated with sexual dysfunction.

1976/about 300 pages/illustrated/$14.95

Human Sexuality
A Health Practitioner's Text
by Richard Green, M.D.

An unusual sourcebook with strong clinical flavor, this book is aimed at the physician, medical student, or other health service professional needing a quick reference for use in counseling patients with sex oriented questions or complaints.

Green provides factual information on birth control, homosexuality, sex assignment, heterosexual relationships, and sexual behavior during pregnancy and in cardiac or mentally retarded patients. Throughout the text, he emphasizes the importance of attitudes and techniques that will serve the patient's need for dignity and the clinician's need for gathering information.

The increased sensitivity and adequacy of response that can be achieved through an understanding of human sexuality as revealed in these pages will permit the physician to offer honest sexual advice, free of the distortion of moral judgement.

1975/312 pages/illustrated/$14.50 (hardbound), $9.50 (paperbound)

Comprehensive Textbook of Psychiatry II (CTP-II)
edited by Alfred M. Freedman, M.D., Harold T. Kaplan, M.D., and Benjamin J. Sadock, M.D.

In this two volume, second edition of the highly regarded COMPREHENSIVE TEXTBOOK OF PSYCHIATRY, the editors have successfully performed the prodigious task of molding the knowledge and experience of more than 200 distinguished practicing psychiatric scholars into a new standard for comprehensive texts. This is one of those rare works that actually lives up to the promise of its title in that it presents the full scope of its subject from a theoretical as well as a clinical perspective.

This truly encyclopedic reference has already been recognized as the one title just as indispensable to the student as it is to the established practitioner or teacher. The achievement of CTP-II will be of interest to everyone concerned with the foundations, progress, and future of contemporary psychiatry.

1975/3000 pages/471 illustrations/$65.00

Medical Aspects of Human Sexuality
750 Questions Answered By 500 Authorities
compiled by Harold I. Lief, M.D.

MEDICAL ASPECTS OF HUMAN SEXUALITY was written on the premise that sex related problems are the proper concern of everyone caring for the psychological or physiological well being of their patients. Neither didactic nor casual in approach, it provides authoritative responses to the questions most frequently encountered in daily practice. The question and answer format permits the inclusion of several views on those problems for which empirical studies have provided inconclusive results.

In this thorough and sensitive collection of informed dialogue from the journal of the same name, every detail of the sexual experience is considered. The topics range from basic questions on physiology and anatomy to the complex issues involved with sexual dysfunction, deviancy, marital relationships, venereal disease, and sex roles in modern society.

For the concerned practitioner, student, or researcher it will prove to be an excellent source of straightforward, factual assistance.

Loxitane®
LOXAPINE SUCCINATE
Lederle

Exhibited certain favorable trends in side effects profile

IN 31 STUDIES INVOLVING 469 ACUTE AND CHRONIC CHIZOPHRENIC PATIENTS, CERTAIN FAVORABLE TRENDS WERE EXHIBITED IN THE OXITANE SIDE EFFECTS PROFILE; THESE REQUIRE FURTHER TESTS AND BROADER LINICAL EXPERIENCE FOR CONFIRMATION.

While cardiac arrest, blood dyscrasias and renal toxicity have been reported with other antipsychotic agents, they have not been seen with LOXITANE. Hepatotoxicity manifested by jaundice or biliary stasis has not been observed. Transient liver enzyme changes, however, have been reported, but it has not been determined whether they are related to LOXITANE administration.

Although a few cases of changes in ECG have been reported, a causal relationship between this reaction and LOXITANE has not been established. Clinical experience with LOXITANE has not demonstrated ocular toxicity; however, the possibility of its occurrence cannot be ruled out at this time. Of the various endocrine abnormalities, only galactorrhea has been reported with LOXITANE and only in rare instances. Manifestations of adverse effects on the central nervous system other than extrapyramidal symptoms have been encountered infrequently, and drowsiness, when it occurs, is usually mild and subsides with continued therapy. Skin rashes of uncertain etiology have been observed in a few patients during the hot summer months; therefore the possibility of phototoxicity and/or photosensitivity cannot be excluded.

In general, LOXITANE presents a profile of extrapyramidal side effects similar to that of other agents used in the treatment of schizophrenia.

Cardiovascular effects such as hypotension, hypertension, lightheadedness and syncope have been reported. Anticholinergic effects seen with LOXITANE include dry mouth, nasal congestion, constipation and blurred vision.

nings and precautions and for more detailed information concerning side effects.

PRODUCT INFORMATION

DESCRIPTION

LOXITANE *loxapine*, a dibenzoxazepine compound, represents a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines. Chemically, it is 2 - chloro - 11 - (4 - methyl - 1 - piperazinyl) dibenz [b,f] [1,4] oxazepine. It is present in capsules as the succinate salt. Each 1.36 mg of loxapine succinate is equivalent to 1 mg of loxapine.

ACTIONS

Pharmacologically, loxapine is a tranquilizer for which the exact mode of action has not been established. However, changes in the level of excitability of subcortical inhibitory areas have been observed in several animal species in association with such manifestations of tranquilization as calming effects and suppression of aggressive behavior.

In normal human volunteers, signs of sedation were seen within 20 to 30 minutes after administration, were most pronounced within 1½ to 3 hours, and lasted through 12 hours. Similar timing of primary pharmacologic effects was seen in animals.

Absorption of loxapine following oral or parenteral administration is virtually complete. The drug is removed rapidly from the plasma and distributed in tissues. Animal studies suggest an initial preferential distribution in lungs, brain, spleen, heart, and kidney. Loxapine is metabolized extensively and is excreted mainly in the first 24 hours. Metabolites are excreted in the urine in the form of conjugates and in the feces unconjugated.

INDICATIONS

LOXITANE *loxapine succinate* is indicated for the manifestations of schizophrenia.

CONTRAINDICATIONS

LOXITANE is contraindicated in comatose or severe drug-induced depressed states (alcohol, barbiturates, narcotics, etc.)

LOXITANE is contraindicated in individuals with known hypersensitivity to the drug.

WARNINGS

Usage in Pregnancy: Safe use of LOXITANE *loxapine succinate* during pregnancy or lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the benefits of treatment be weighed against the possible risks to mother and child. No embryotoxicity or teratology was observed in studies in rats, rabbits or dogs, although with the exception of one rabbit study, the highest dosage was only two times the maximum recommended human dose and in some studies they were below this dose. Perinatal studies have shown renal papillary abnormalities in offspring of rats treated from midpregnancy with doses of 0.6 and 1.8 mg/kg, doses which approximate the usual human dose but which are considerably below the maximum recommended human dose.

Usage in Children: Studies have not been performed in children; therefore this drug is not recommended for use in children below the age of 16.

LOXITANE, like other tranquilizers, may impair mental and/or physical abilities, especially during the first few days of therapy. Therefore, ambulatory patients should be warned about activities requiring alertness (eg, operating vehicles or machinery), and about concomitant use of alcohol and other CNS depressants.

PRECAUTIONS

LOXITANE loxapine succinate should be used with extreme caution in patients with a history of convulsive disorders since it lowers the convulsive threshold. Seizures have been reported in epileptic patients receiving LOXITANE at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy.

Loxapine has an antiemetic effect in animals. Since this effect may also occur in man, loxapine may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

LOXITANE should be used with caution in patients with cardiovascular disease. Increased pulse rates have been reported in the majority of patients receiving antipsychotic doses; transient hypotension has been reported. In the presence of severe hypotension requiring vasopressor therapy, the preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine.

The possibility of ocular toxicity from loxapine cannot be excluded at this time. Therefore, careful observation should be made for pigmentary retinopathy and lenticular pigmentation since these have been observed in some patients receiving certain other antipsychotic drugs for prolonged periods.

Because of possible anticholinergic action, the drug should be used cautiously in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinson medication.

ADVERSE REACTIONS

CNS Effects: Manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently. Drowsiness, usually mild, may occur at the beginning of therapy or when dosage is increased.

It usually subsides with continued LOXITANE therapy. The incidence of sedation has been less than that of certain aliphatic phenothiazines and slightly more than the piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported.

Extrapyramidal Reactions—Neuromuscular (extrapyramidal) reactions during the administration of LOXITANE *loxapine succinate* have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved Parkinson-like symptoms such as tremor, rigidity, excessive salivation, and masked facies. Akathisia (motor restlessness) also has been reported relatively frequently. These symptoms are usually not severe and can be controlled by reduction of LOXITANE dosage or by administration of antiparkinson drugs in usual dosage. Dystonic and dyskinetic reactions have occurred less frequently, but may be more severe. Dystonias include spasms of muscles of the neck and face, tongue protrusion, and oculogyric movement. Dyskinetic reaction has been described in the form of choreo-athetoid movements. These reactions sometimes require reduction or temporary withdrawal of LOXITANE dosage in addition to appropriate counteractive drugs.

Persistent Tardive Dyskinesia—As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movement of the tongue, face, mouth, or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinson agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Cardiovascular Effects: Tachycardia, hypotension, hypertension, light-headedness, and syncope have been reported.

A few cases of ECG changes similar to those seen with phenothiazines have been reported. It is not known whether these were related to loxapine administration.

Skin: Dermatitis, edema (puffiness of face), pruritus, and seborrhea have been reported with loxapine. The possibility of photosensitivity and/or phototoxicity occurring has not been excluded; skin rashes of uncertain etiology have been observed in a few patients during hot summer months.

Endocrine Effects: No endocrine abnormalities have been reported.

Anticholinergic Effects: Dry mouth, nasal congestion, constipation, and blurred vision have occurred; these are more likely to occur with concomitant use of antiparkinson agents.

Other Adverse Reactions: Nausea, vomiting, weight gain, weight loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, and polydipsia have been reported in some patients.

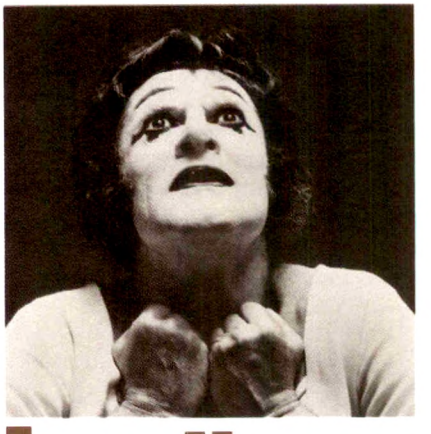
DOSAGE AND ADMINISTRATION

LOXITANE *loxapine succinate* is administered orally usually in divided doses two to four times a day. Daily dosage (in terms of base equivalents) should be adjusted to the individual patient's needs as assessed by the severity of symptoms and previous history of response to antipsychotic drugs. Initial dosage of 10 mg twice daily is recommended, although in severely disturbed patients initial dosage up to a total of 50 mg daily may be desirable. Dosage should then be increased fairly rapidly over the first seven to ten days until there is effective control of psychotic symptoms. The usual therapeutic and maintenance range is 60 mg to 100 mg daily. However, as with other antipsychotic drugs, some patients respond to lower dosage and others require higher dosage for optimal benefit. Daily dosage higher than 250 mg is not recommended. For maintenance therapy, dosage should be reduced to the lowest level compatible with symptom control; many patients have been maintained satisfactorily at dosages in the range of 20 mg to 60 mg daily.

HOW SUPPLIED

LOXITANE *loxapine succinate* is supplied in the following base equivalent strengths:

CAPSULES Hard Shell Printed "Lederle"



10 mg—Green and Yellow; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5360.

25 mg—Green Two Tone; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5361.

50 mg—Green and Blue; Bottles of 100, 1000, and unit dose 10 x 10's—Product Number 5362.

RESULTS OFTEN SEEN IN A WEEK

Because the somatic and psychic complaints that accompany depressive neurosis can interfere with the treatment of the underlying psychopathology—rapid relief of these symptoms is often crucial to therapy.

In 14 double-blind studies of four weeks duration, 339 patients with depressive neurosis received Mellaril. In these studies, 55% of the overall improvement was observed by the end of the first week, and a total of 293 patients (86%) improved during the four weeks.*

Mellaril usually does not cause euphoria or undue sedation and is nonaddicting. Patients, therefore, generally remain alert and better able to respond to therapy. (The physician should, however, caution patients against participating in activities which require complete mental alertness, e.g., driving.)

*Data on file at Sandoz Pharmaceuticals.

MELLARIL®
(THIORIDAZINE)

TABLETS: 25 mg and 50 mg thioridazine HCl, U.S.P.

for the short-term treatment of moderate to marked depression with variable degrees of anxiety in patients with depressive neurosis

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling. The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign. and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Dosage: Dosage must be individualized according to the degree of mental and emotional disturbance, and the smallest effective dosage should be determined for each patient. In adults with depressive neurosis the usual starting dosage is 25 mg t.i.d. and the dosage ranges from 10 mg b.i.d. to q.i.d. in milder cases to 50 mg t.i.d. or q.i.d. for more severely disturbed patients; the total daily dose ranges from 20 mg to a maximum of 200 mg.

THE AMERICAN JOURNAL OF PSYCHIATRY

The Life of Psychiatry

BY BERTRAM S. BROWN, M.D.

Focusing on the definition, scope, and role of psychiatry today, the author discusses whether psychiatry is primarily medical, whether it is overstepping its boundaries in attempting to treat problems of living, and whether it is too involved with social questions. On the basis of an examination of the current scientific base of psychiatry, he predicts that psychiatry will continue to grow in size and diversity, that it will refocus substantially on biological issues, that it will become more humble about what it can do with regard to social problems, and that it will continue to yield new therapeutic measures and techniques.

THIS PERSPECTIVE on the life of psychiatry is both personal and professional, drawing on both my evolving self-concept as a psychiatrist and my role as director of the National Institute of Mental Health. Although I will focus on psychiatry, many of my comments apply to the broad field of mental health. To write a truly comprehensive and current paper on this field is difficult. Therefore, I will discuss briefly or omit several important areas, such as the potential impact of national health insurance, the role of Professional Standards Review Organizations (PSROs), the new health planning legislation (Public Law 93-641), and other critical areas. Rather, I will attempt to focus on some of the potentials and limits of psychiatry at a time when the resiliency of the profession is being tested by calls for both expansion and contraction. The simple fact that many of these calls originate within the profession will make the proof of the test all the more crucial.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Brown is Director, National Institute of Mental Health, Alcohol, Drug Abuse, and Mental Health Administration, 5600 Fishers Lane, Rockville, Md. 20852.

I would like to highlight a particular evolution that has taken place. Twenty-five years ago, when our predecessors spoke of psychiatry they were also speaking of the broader field of mental health. What they and their contemporaries termed "mental health" some leaders today term "human services." Many of these leaders are psychiatrists, but the issue of how much psychiatry represents mental health and how much mental health represents human services is at the heart of the great debate concerning the role, definition, scope, and boundaries of psychiatry.

The same issue applies to NIMH. There is a "strict constructionist" view of the mission of NIMH that emphasizes health sciences; there is also a broad view that emphasizes human services and other social missions.

What is the role of psychiatry? Does it even have a role, or is it, as some would have it, dead or dying? Is it perhaps gathering strength? What is the nature of its identity crisis? What are its prospects?

COMPARISONS WITH GENERAL MEDICINE

Measured by the sheer number of practitioners,[1] psychiatry has had an astonishing growth since 1939. In that year there were about 3,000 psychiatrists (2.3 per 100,000 of the population of the United States). Most of them were called "alienists." In 1948, when NIMH was founded, there were 4,700. In 1950 there were 7,100 (4.7 per 100,000). By 1960 this number had almost doubled to 14,000 (7.7 per 100,000). During the decade of the 1960s the number of psychiatrists increased by 65% to 23,200 in 1970 (11.3 per 100,000). Today there are 27,000 psychiatrists in the United

[1]Data on the number of psychiatrists before 1960 were compiled from records on APA membership and filled psychiatric residencies. Data on psychiatrists and other physicians for 1960 to 1973 are based on *Distribution of Physicians in the United States* (1). I have estimated the projection for 1980, taking into consideration the number, production, and attrition of practicing psychiatrists today.

States.[2] Estimating according to the number of potential psychiatrists in the educational system now, there will be 30,000 by 1980 (17.8 per 100,000).

Thus the number of psychiatrists has increased by 16% in the past 5 years and 45% in the past 10 years. Since the founding of NIMH it has increased more than fivefold.

How does this compare with general medicine? In the decade from 1963 to 1973 the total number of nonpsychiatrist physicians increased by 81,422, from 259,894 in 1963 to 341,316 in 1973, an increase of 31.3%. During the same decade the number of psychiatrists increased by 8,482, from 16,581 to 25,063, an increase of 51.2%. Additionally, the proportion of psychiatrists in the total number of physicians increased by 0.8%, from 6.0% to 6.8%.

A comparison with other specialty groups shows that psychiatry's growth during 1963 through 1973 was the third largest. It was surpassed only by internal medicine, which increased by 2.7%, and by radiology, which increased by 1%.

However, the number of psychiatric residents in the United States today has reached a plateau. According to data from APA and the American Medical Association (AMA), the number of residents in training in 1972 was 4,699, in 1973 it was 4,739, and in 1974 it was 4,802. Approximately 1,000 American medical school graduates were in the first year of psychiatric residency in September 1972, representing 10.5% of the graduating class. In September 1974, there were again about 1,000 graduates who were in the first year of psychiatric residency. However, these residents represented only about 8.9% of a larger graduating class. Although the number remained approximately the same, the proportion of medical school graduates entering psychiatric residency dropped by approximately 15% between 1972 and 1974.

One feature of medicine in general that applies dramatically to the statistics on the number of psychiatrists is the role of foreign medical graduates. According to data from APA and AMA, foreign medical graduates constituted 32% of all psychiatric residents in 1974. They now comprise more than 50% of the psychiatrists in practice in many state institutions; in a few states their proportion in these hospitals nears 100%.

Activities in Congress, in the states, and in professional organizations that may limit the immigration or the ability to practice of foreign medical graduates will have an immediate and severe impact on patient care. The issue of the willingness of other psychiatrists to work in state institutions will stand out clearly if foreign medical graduates are excluded from these jobs.

About 1,500 psychiatrists in the United States complete their residency training each year, and about 850 leave active practice. Thus about 750 psychiatrists are annually added to the national total.

It is generally estimated (2) that about half of all psychiatrists active today are in general psychiatry, 13% deal with adults, 10.5% specialize in psychoanalysis, and just over 9% are in child psychiatry. Somewhat more than 4% work in community or social psychiatry, and only 0.5% report specializing in geriatric psychiatry.

Another aspect of these numbers and proportions is extremely interesting. A 1972 NIMH survey of psychiatrists (3) showed that the percentages of psychiatrists from minority groups were relatively small—1.4% were black, 1.5% were Spanish-American, and 1.3% were from other minority groups. Although earlier figures are not readily available for comparison, the proportion of minority psychiatrists is apparently growing, albeit slowly.

For yet another perspective on the issue of numbers, consider the distribution of psychiatrists per 100,000 population in this country (2). Eleven states, including South Dakota, Wyoming, and Alabama, have less than 5 psychiatrists for every 100,000 people. Twenty states, including Alaska, Maine, Minnesota, and Virginia, have more than 5 but less than 8 psychiatrists per 100,000. In 8 states the ratio is at least 12 psychiatrists per 100,000. New York State has 25, Massachusetts has 22, Connecticut has 20, Maryland has 19, Vermont and California have 17 each, Colorado has 15, and Hawaii has 13. The average number of psychiatrists per 100,000 population for the entire United States is 11.9.

The District of Columbia stands head and shoulders above the other states in terms of number of psychiatrists. Its ratio is 58 psychiatrists per 100,000 people—more than double that of New York State and more than quadruple the average. The numbers do not include the more than 2,200 psychiatrists who work for the federal government in the District of Columbia.

The wide variation in number of psychiatrists per 100,000 people among the states is important. The figures range from 5 to more than 50; i.e., one state has more than 10 times as many psychiatrists per 100,000 people as another. When rural areas are distinguished from metropolitan areas and those in between in each state, one finds that some areas have 20 to 30 times as many psychiatrists per 100,000 people as other areas. These ranges underlie the issues pressing at health and mental health manpower legislation. The term now most commonly used to describe this situation is "maldistribution."

PSYCHIATRIC TRAINING

The recent policy shifts in psychiatric training have been among the most dramatic in the history of all professional training. Several years ago the various professional associations engaged in vigorous debate over the requirement of a medical internship for medical

[2]Although there are no hard data on the number of psychiatrists in the world today, information from the World Health Organization and the World Psychiatric Association indicate that the figure is between 75,000 and 100,000. Thus the United States has between one-quarter and one-third of the world's psychiatrists.

school graduates planning to enter psychiatry. Two polarities of opinion emerged. One group held that dropping the internship would be a dreadful mistake, and the other felt that most of a medical internship was irrelevant to psychiatric practice and should be dropped. The latter position ultimately won, and the American Board of Psychiatry and Neurology dropped the internship requirement.

During the next year or so we will undoubtedly see a reversal of this policy and a reinstitution of the internship or an internship-like experience as either a prerequisite to or the initial part of psychiatric residency training. It is important to note that the experience of caring for a variety of patients with serious physical illnesses rather than the loss of a year called an "internship" has been the missing ingredient.

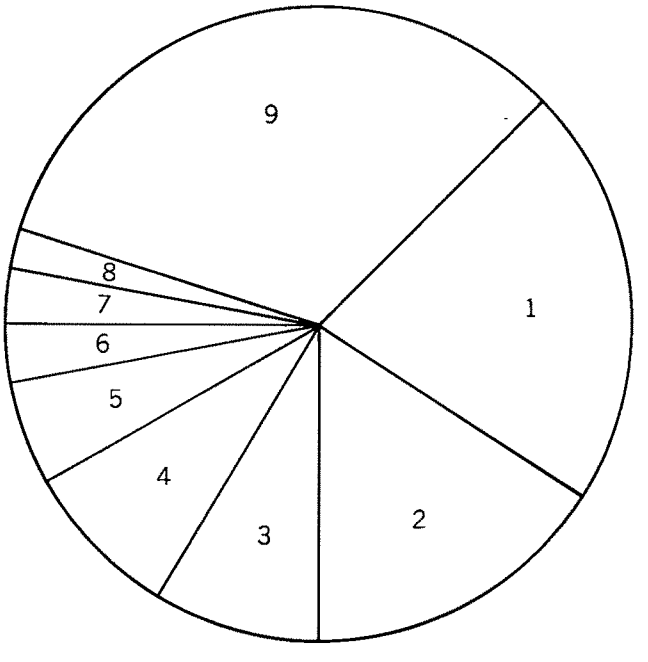
In a practical sense, the movement of psychiatry back into the health arena is more than a conceptual issue. It is a descriptive issue on the current educational scene.

Along with the increase in the number of psychiatrists there has been an increase in the number of residency programs (4). There were 270 residency programs in the United States in 1973, representing positions for 4,992 residents; 4,131 of these positions (86%) were filled. The residency programs ranged from those which were highly clinically oriented to those which worked with chronic patients in state institutions to those which were psychodynamically oriented university programs. Moreover, these programs of psychiatric training and education were not limited to psychiatrists. Training in psychiatry and behavioral sciences has been provided to nonpsychiatric physicians, particularly those providing primary care, and to other mental health professionals.

Of even greater importance is the provision of psychiatric, behavioral, and social science training for medical students. Every medical school now has a department of psychiatry. In the future, programs in psychiatry and behavioral and social sciences will be provided and emphasized in all of the stages in the education of medical students.

THE PATIENT POPULATION

The heart and the end point of the issues of scope and definition are in psychiatry's interaction with patients and other people. The context of the following patient population statistics is traditional, including the services of state and Veterans Administration hospitals, outpatient clinics, and community mental health centers. The numbers of patients are somewhat understated because they do not include those seen by psychiatrists in private practice and by other mental health professionals. Also not included are family service agencies or what I call "fringe groups," the plethora of sensitivity training groups, experimental programs, and other encounter sessions and seminars.



In 1955, about 1.7 million people (1% of the total U.S. population) had some contact with the mental health care system (5). By the mid-1960s this number had increased to 2.6 million (1.4% of the population). Our most recent figure (for 1971) is more than 4 million (2.4% of the population). These figures represent all patient care episodes and include some duplication.

A conservative estimate for 1975 would be 5 million to 6 million people in contact with the mental health care system. The diagnostic categories of those who were receiving some kind of treatment in 1971 (6) included schizophrenia (22.5%), depressive disorder (15.4%), alcohol disorder (8.8%), organic brain syndrome (5.4%), mental retardation (3.1%), drug disorder (2.9%), and psychosis other than schizophrenia and depression (1.5%). All other diagnoses totaled 32.4%, and 8% of the patients were undiagnosed (see figure 1).

The national utilization rate, the percentage of the population that in a given year comes to the attention of the formal mental health care system, was about 2% or 2.5% in 1971 (5). These contacts may be as brief as 10 minutes in the emergency room of a hospital or as long as the entire year in an inpatient unit.

The range of utilization rates in different parts of the United States is somewhat similar to the distribution of psychiatrists. The utilization rate in rural parts of

FIGURE 1
Distribution of Diagnoses of More Than 4 Million Patients Who Had Contact with the Mental Health Care System in 1971 (6)

1: Schizophrenia (22.5%)
2: Depressive disorder (15.4%)
3: Alcohol disorder (8.8%)
4: Undiagnosed disorder (8.0%)
5: Organic brain syndrome (5.4%)
6: Mental retardation (3.1%)
7: Drug disorder (2.9%)
8: Psychosis other than schizophrenia or depression (1.5%)
9: All other disorders (32.4%)

the country, which have about 5 psychiatrists per 100,000 people, is 0.5% to 0.75%. The utilization rate of such urban areas as San Mateo County, midtown Manhattan, and the suburbs of Washington, D.C., is about 7% or 8%. This disparity is behind the demands of both liberals and conservatives to improve access to mental health care and to meet the criterion of equity.

Looking at this situation most conservatively, i.e., projecting a 1% increase in the national utilization rate, continued support for training at no less than the present level, and no fewer entrants into the profession, we can predict a shortage of nearly 10,000 psychiatrists by 1981.

The forces behind the increased utilization rates are related to the purchasing power that is now available through third-party financing. The rates will increase even more with the passage of some form of national health insurance in the near future. They are also related to the fact that seeking psychiatric assistance has less of a stigma attached to it today.

A LOOK AT THE PROFESSION

I want to emphasize that there are different types of psychiatrists, that their training experiences are diverse, and that the types of patients they see are also diverse. This is another reflection of the issues of scope, definition, and role.

I believe that psychiatry faces less danger from adversity than it does from diversity. Although diversity is a danger, it is much more a sign of growth and experimentation, a developmental process that relates clearly to the history of our evolving specialty and the state of our scientific knowledge. A healthy and sound aspect of diversity is that it results in a focusing and narrowing of our skills. Each type of psychiatry may treat the very persons who need and benefit from that special focus of experience and approach.

The following seven types of psychiatrists comprise a loose, non-mutually-exclusive typology:

Type 1, the neuropsychiatrist, is rapidly becoming a vanishing breed. This is the pragmatic clinical practitioner who is as comfortable with neurology as with psychiatry. His patients range from the simply troubled to the severely ill, and he may see patients for brief counseling or hospitalize them. He may use convulsive therapy; he may prescribe drugs.

I recently checked on the number of people who took Board examinations in both neurology and psychiatry in 1973 and 1974. According to data from APA, several hundred took one or the other and passed; the number who took both in 1974 can be counted on one hand. Two or three decades ago, however, the majority of psychiatrists took both examinations.

My type 2 psychiatrist—the psychodynamically oriented psychotherapist—seemed on the path to dominance only a short time ago. This psychiatrist may see patients one to three times a week over a period of 6 months to 2 years or more. Steeped in psychoanalytic theory, he concentrates on an office practice; although he may hospitalize his patients occasionally, he usually transfers patients needing hospitalization to a colleague. The frequency of this type of psychiatrist is leveling off.

The psychoanalyst, type 3, has taken full psychoanalytic training and practices psychoanalysis predominantly. He may have 5 to 15 patients and may allocate a small proportion of his time to consultation or other outside activities. Because this type of psychiatrist was dominant, from 1945 to 1955 it was nearly impossible for a nonpsychoanalyst to become chairman of a department or professor of psychiatry. Today the number of psychoanalysts is dwindling, and an exclusively psychoanalytic psychiatrist is rarely found at the head of a department of psychiatry.

Type 4, the biological psychiatrist, includes some of the brightest young people in the country. Skilled in the psychobiological sciences, this cadre is changing the profession as a whole and influencing society.

My type 5 is the child psychiatrist. Many child psychiatrists were pediatricians before turning to psychiatry. The growth of child psychiatry as a specialty has been phenomenal. According to data from AMA, there were 751 child psychiatrists in the United States in 1963; in 1973 there were 2,362. This represents a growth rate of 200%. General psychiatry's growth rate was 46% during the same period.

I would classify type 6 as the social psychiatrist—the program administrator or the director of a mental health center or a new alcoholism or drug abuse endeavor. His work is at the interface of troubled behavior and social systems.

Finally, there is type 7, which I call the "experimental" or "fringe" group. This psychiatrist uses a variety of techniques and is often found in unusual places doing unusual things. This is a critically important group because when the fads filter out and the charlatans and phonies take their leave, type 7 promises to be the wave of the future. If we look carefully at the history of psychiatry we find that there have always been elements in the fringe and experimental groups that have had more influence ultimately than was generally recognized at the time.

KEY ISSUES

The major issues I have focused on have to do with the definition, scope, and role of psychiatry. The critical subissues are whether psychiatry is primarily medical and therefore concerned with taking care of the seriously clinically sick, whether psychiatry is overdoing its task in attempting to treat those with transient or less severe clinical problems, and whether psychiatry is too involved in social questions.

Thus the issues center around three categories of people—the very sick and psychotic patients, those who are greatly handicapped by emotional and psychological disturbances, and those who are experiencing

problems of living, for whom the desired quality of life has proved elusive.

It is around these groups that the tensions in our field are being generated; two points of view seem to predominate. There are those who believe that psychiatry has clearly bitten off more than it can chew and ought to get back to treating serious mental illness, and there are those who feel that unless we work to change social systems we shall inevitably have a continuing flow of sick and troubled people.

I realize that people at both ends of this spectrum are keenly aware that the intermediate zone is one of great diagnostic difficulty. It takes skill and knowledge to ascertain what might be a life problem and what might be the earliest signs of an oncoming depression or other mental illness. Such diagnostic requirements demand that we take an extensive look at our clinical and scientific base and what we do or do not know about prevention.

THE SCIENTIFIC BASE

It is one thing to have a value base for what we think we should do, but it is quite another to have a scientific base—an objective set of measures about whether what we do is effectively achieving what we set out to do. Psychiatry has been a major service-providing instrument of that vital and nourishing enterprise we call mental health research. Psychiatry has played a significant but smaller role in the actual conduct of research. Only a few psychiatrists—numbering in the hundreds—are full-time researchers. This is a vital area of debate as we deliberate over the nature of financial support policies in research in general and psychiatry in particular. In their roles as conceptual, clinical, and program leaders, psychiatrists have played a leading role in stimulating and supporting research endeavors by other mental health professionals and behavioral and social scientists.

At NIMH we have just finished a 2-year effort by a research task force that involved 300 people and $1 million to review $1 billion worth of research in the United States supported by NIMH and others.

The report (7) shows that the number of research projects supported annually by NIMH has grown from 38 in 1948, when the first appropriations were made under the National Mental Health Act of 1946, to nearly 1,500 in 1975. About 30% of the total NIMH research budget has been devoted to research in the biomedical and behavioral sciences, including studies designed to identify physiological, psychological, social, and cultural factors that shape human behavior. Out of this effort has emerged work of enormous relevance, not only for enlarging our understanding of human behavior but for productive clinical research as well.

The task force report will vitalize debates now under way as to the nature and scope of the psychiatric research enterprise, including such issues as balance and priorities. To some degree, these are but other ways of looking at the scope and definition of psychiatry itself. A brief example will suffice: over the last 20 years we have seen the ratio of the amount of NIMH-supported biomedical research to psychosocial research reversed; 20 years ago the ratio of biomedical research to psychosocial research was 2 to 1; in 1975 it was 1 to 2.

This dramatic shift reflects the broadening of NIMH's mission in the late 1960s into social problem areas such as crime and delinquency. Within the mental illness sphere of the NIMH program, biomedically oriented research continues to be predominant but with an increasingly fine line of distinction between the two approches.

The Subjective Approach

One of the ways I have approached the issue of psychiatry's scientific base is to return to the subjective. For example, when I really wonder about the depth and wisdom of my opinion or judgment on a given situation, I ask what I want for myself, my wife, my children, my parents. Some of the answers that emerged for me follow:

1. I would much rather have a mid-life depression today than 20 years ago (assuming my present age both now and then) because of the current advances in the treatment of depression and acute depression, the understanding of its biology, and the availability of drugs.

2. I think I would rather one of my children have an acute schizophrenic break now than 20 years ago. I will not go farther because I know the complexities surrounding schizophrenia, and I do not say this with quite the certainty that I use in discussing mid-life depression. However, I think we have made enough advances in the treatment of acute schizophrenia that the scientific base is ahead of that of 20 years ago.

3. Suppose my marriage were in serious trouble, with agony, misery, sleeplessness, concern, trouble with the children, and job trouble. Would I be any better off being treated by a psychiatrist today than I would have 20 years ago? I think not. The best possible source for help for me in this situation would be a mature, wise psychiatrist. There has been an increment of knowledge in the area of marital and family therapy, but that increment is small compared with what is known or needs to be known. The critical variable today is the same as it was 20 years ago—the maturity and wisdom of the helping person.

The research task force (7) found that research investments in the area of helping the practitioner deal with troubled people have not yielded a cornucopia of techniques or programs. To realize our hopes and expectations in this area we must reassess what we have been doing, decide what we have been doing incorrectly, and ascertain what we can do better.

The relatively low yield in social research may be due to many factors. It may be that we are just now

building the base in this complex field so that workers in the next decade or so may provide useful answers. It may be that the methodologies necessary to get answers in the area of social problems are so complex that we have yet to develop effective tools. There are those who would have us abandon this area altogether. This I cannot support. To do it better—perhaps even to make use of some of the resources from more promising areas—makes sense, but to do nothing seems both unprofessional and unwise.

A Look at Possibilities

Let me now move from my subjective position to a more general frame of reference:

1. My answer to the question of whether psychiatry is up to the task of dealing with serious mental illness and whether it is doing the job has to be yes. Emphatically, however, I must add that we are not doing it perfectly, nor are we doing enough of it, given our knowledge base. In spite of our advances in knowledge and the addition of chemotherapy to our armamentarium, we must still wait for research to uncover some basic unknowns. Even so, we could do it better if we made the best use of what we know now, particularly about community treatment and care.

2. My answer to whether psychiatry is dealing effectively with that 5% or 10% of the population who are not psychotic but who are very troubled, whose functioning is disturbed, or who are on the verge of becoming disturbed also has to be yes. However, I must add that the gains in this area have been less significant than the gains in the biological area in the struggle against schizophrenia and psychotic depression.

3. My best answer to whether psychiatry's scientific base regarding the treatment of the unhappy, the alienated, and the troubled has increased in the past 20 years is that it has increased very little.

For example, are people who have been laid off from work better off today than those who lost their jobs in the 1930s? In one sense, of course, with unemployment insurance and other social benefits, the outlook for economic recovery is considerably better than it was then, but are these people better off in terms of what psychiatry has to offer?

Many more people who develop troubling symptoms ask for help today than asked for it in the 1930s, perhaps for no other reason than that it is so much more available. However, only a minimal amount of knowledge has accumulated—beyond our increased ability to care for the mentally or emotionally disabled—to strengthen our capacity for dealing with the unemployment problem as it affects the emotional well-being of the individual.

When it comes to the question of whether psychiatry *should* treat people with problems of living, one of the most powerful dynamics is the great influence of the dollar. If the troubled are willing to pay, and the psychiatrist is willing to accept, the question becomes moot.

What Lies Ahead?

On the basis of the research task force report (7) and the knowledge my colleagues and others in the field have gained, I predict in complete confidence that psychiatry will continue to grow in size and diversity.

There is no sign at present that there is a lack of growth in the size of psychiatry or that the demand for its services is decreasing. Any profession that is growing in size, that is having more and more demands put on it, and that has such a diversity in training programs, types of practitioners, and therapeutic techniques is not a dying profession.

By reason of the nature of psychiatry's scientific base and its cultural connection to medicine, I also predict that the profession will refocus to a significant extent on clinical—and particularly biological—psychiatry, that it will become more humble about what it can do in regard to social problems and issues, and that it will continue to yield new experimental therapeutic measures and techniques. Most of these will fall by the wayside, but a few should lead to more effective treatment.

For the rest of this century and probably well into the next, treating the hard core of mental illness—the schizophrenias and the depressions—and dealing with troubled behavior that is or threatens to become incapacitating will continue to be vital activities in the thriving profession of psychiatry.

The psychiatrist will continue to be called on to help with problems of living that are less serious but more widespread. However, so will the psychologist, the social worker, the psychiatric nurse, the educator, the clinical sociologist, the clergyman, and others who for years have been working in this area.

In other words, psychiatry can expect to find itself in collegial competition with other professions and, perhaps, with paraprofessionals in the treatment of people whose problems in living are not associated with serious clinical illness.

From the standpoint of the patient, or the client, there may be two strong reasons for going to a skilled problems-of-living psychiatrist rather than to another mental health professional. One is to enjoy whatever protection can be assumed to lie in the M.D. degree—the ethics and the traditions associated with medicine for thousands of years. The other is to benefit from the greater diagnostic acumen that the psychiatrist has, or should have, in case of an underlying biological condition requiring attention. When there is no such condition, the wise pastoral counselor, the humanistic psychologist, and the warmhearted psychiatrist may be equally effective; the results depend more on the quality and less on the type of training of the human beings who serve as therapists or counselors. In the final analysis, the patient, the consumer, will make the final judgment.

In 1949 I had the privilege of hearing David Wechsler, who developed the Wechsler Adult Intelligence Scale, give a lecture on the future of psychology. He

discussed the then red-hot issue of whether psychologists could do psychotherapy. He predicted the resistance of psychiatrists. He also predicted that the issue would not be settled at an American Psychiatric Association meeting or at an American Psychological Association meeting but "in the American marketplace."

I believe that the question of who will deal with the most pervasive, although relatively minor, of our mental health problems will be decided in the marketplace. If the nonmedical worker proves as acceptable and efficacious as the physician as well as less expensive, psychiatry can be expected to play less of a role in treating the so-called problems of living. In the treatment of serious mental illness, however, psychiatry is likely to remain dominant.

CONCLUSIONS

Psychiatry is growing in size, absolutely as well as in relation to general medicine. Although from the production point of view it has passed its peak growth, I expect psychiatry will continue to grow into the mid-1980s.

Psychiatry is growing in diversity. Parts of the profession are returning to basic biological and medical foundations; parts are undistinguishable in practice from other mental health professions; parts are under attack, and the outcome is unclear—particularly in social psychiatry. A critical area is the future of child psychiatry—or general psychiatry's role in dealing with families and children.

Psychiatry is undergoing severe criticism from within and without, but the demand for psychiatric services has shown no concomitant diminution and none is in sight.

In my opinion the test of the marketplace, both in the quality of the product and people's willingness to pay, is such that it would be unwise to limit psychiatry's services only to the mentally ill, although its responsibility and strength in this area are clear. It would be unwise and grandiose for psychiatry to claim a monopoly on treating the unhappinesses of the human condition, but it will be a challenge to see if the profession is worth its higher fees in this area.

The interface between psychiatry and social systems is an area in which psychiatry has in some ways overpromised. This interface is the site of hope for integrating prevention efforts with social concerns, for integrating scientific knowledge with humanistic concerns, and, in my opinion, it is a proper domain of psychiatry.

Finally, let me describe a more personal conclusion. I have been practicing something that has been loosely called "political psychiatry." Without bombast, this concerns my having been an administrator dealing with executive, legislative, judicial, and other affairs—serving as deputy director or director of NIMH for a decade. I think the issue of my accountability within these affairs should be brought out.

I have pondered over the fact that two of the groups now under the most severe attack from the public are politicians and psychiatrists. I think what these two groups have in common is the breakdown in trust on the part of their constituents and patients. The issue of trust is basic not only to psychiatry and developmental psychology, but also to the nature of government and governance. Thus it has been my purpose in writing this paper to be as accountable as I can, to state my view, and to continue to welcome dissent and criticism. There are battles to be won or lost in the marketplace, but we must realize we are not battling each other; the fight is on behalf of the mentally ill and in the pursuit of happiness for all.

The Case for Involuntary Hospitalization of the Mentally Ill

BY PAUL CHODOFF, M.D.

The author examines three points of view on the question of society's right to involuntarily hospitalize a mentally ill individual. The "abolitionists" oppose involuntary hospitalization entirely; the medical model psychiatrists support the need for commitment under certain circumstances and so do the civil liberties lawyers, but by different standards. The author believes that with the current overreliance on the dangerousness standard, we are witnessing a pendular swing in which the rights of the mentally ill to be treated and protected are being set aside in the rush to give them their freedom. He favors a return to the use of medical criteria by psychiatrists, albeit with constructive legal safeguards.

I WILL BEGIN this paper with a series of vignettes designed to illustrate graphically the question that is my focus: under what conditions, if any, does society have the right to apply coercion to an individual to hospitalize him against his will, by reason of mental illness?

Case 1. A woman in her mid 50s, with no previous overt behavioral difficulties, comes to believe that she is worthless and insignificant. She is completely preoccupied with her guilt and is increasingly unavailable for the ordinary demands of life. She eats very little because of her conviction that the food should go to others whose need is greater than hers, and her physical condition progressively deteriorates. Although she will talk to others about herself, she insists that she is not sick, only bad. She refuses medication, and when hospitalization is suggested she also refuses that on the grounds that she would be taking up space that otherwise could be occupied by those who merit treatment more than she.

Case 2. For the past 6 years the behavior of a 42-year-old woman has been disturbed for periods of 3 months or longer. After recovery from her most recent episode she has been at home, functioning at a borderline level. A month ago she again started to withdraw from her environment. She pays increasingly less attention to her bodily needs, talks very little, and does not respond to questions or attention from those about her. She lapses into a mute state and lies in her bed in a totally passive fashion. She does not respond to other people, does not eat, and does not void. When her arm is raised from the bed it remains for several minutes in the position in which it is left. Her medical history and a physical examination reveal no evidence of primary physical illness.

Case 3. A man with a history of alcoholism has been on a binge for several weeks. He remains at home doing little else than drinking. He eats very little. He becomes tremulous and misinterprets spots on the wall as animals about to attack him, and he complains of "creeping" sensations in his body, which he attributes to infestation by insects. He does not seek help voluntarily, insists there is nothing wrong with him, and despite his wife's entreaties he continues to drink.

Case 4. Passersby and station personnel observe that a young woman has been spending several days at Union Station in Washington, D.C. Her behavior appears strange to others. She is finally befriended by a newspaper reporter who becomes aware that her perception of her situation is profoundly unrealistic and that she is, in fact, delusional. He persuades her to accompany him to St. Elizabeths Hospital, where she is examined by a psychiatrist who recommends admission. She refuses hospitalization and the psychiatrist allows her to leave. She returns to Union Station. A few days later she is found dead, murdered, on one of the surrounding streets.

Case 5. A government attorney in his late 30s begins to display pressured speech and hyperactivity. He is too busy to sleep and eats very little. He talks rapidly, becomes irritable when interrupted, and makes phone calls all over the country in furtherance of his political ambitions, which are to begin a campaign for the Presidency of the United States. He makes many purchases, some very expensive, thus running through a great deal of money. He is rude and tactless to his friends, who are offended by his behavior, and his job is in jeopardy. In spite of his wife's pleas he insists that he does not have the time to seek or accept treatment, and he refuses hospitalization. This is not the first such disturbance for this individual; in fact, very similar episodes have been occurring at roughly 2-year intervals since he was 18 years old.

Case 6. Passersby in a campus area observe two young women standing together, staring at each other, for over an hour. Their behavior attracts attention, and eventually the police take the pair to a nearby precinct station for questioning. They refuse to answer questions and sit mutely, staring into space. The police request some type of psychiatric examination but are informed by the city attorney's office that state law (Michigan) allows persons to be held for observation only if they appear obviously dangerous to themselves or others. In this case, since the women do not seem homicidal or suicidal, they do not qualify for observation and are released.

Less than 30 hours later the two women are found on the floor of their campus apartment, screaming and writhing in pain with their clothes ablaze from a self-made pyre. One

Revised version of a paper presented at a symposium sponsored by Georgetown University Law School, October 6, 1975.

Dr. Chodoff is Clinical Professor of Psychiatry, George Washington University School of Medicine. He is also in private practice at 1904 R St., N.W., Washington, D.C. 20009.

woman recovers; the other dies. There is no conclusive evidence that drugs were involved (1).

Most, if not all, people would agree that the behavior described in these vignettes deviates significantly from even elastic definitions of normality. However, it is clear that there would not be a similar consensus on how to react to this kind of behavior and that there is a considerable and increasing ferment about what attitude the organized elements of our society should take toward such individuals. Everyone has a stake in this important issue, but the debate about it takes place principally among psychiatrists, lawyers, the courts, and law enforcement agencies.

Points of view about the question of involuntary hospitalization fall into the following three principal groups: the "abolitionists," medical model psychiatrists, and civil liberties lawyers.

THE ABOLITIONISTS

Those holding this position would assert that in none of the cases I have described should involuntary hospitalization be a viable option because, quite simply, it should never be resorted to under any circumstances. As Szasz (2) has put it, "we should value liberty more highly than mental health no matter how defined" and "no one should be deprived of his freedom for the sake of his mental health." Ennis (3) has said that the goal "is nothing less than the abolition of involuntary hospitalization."

Prominent among the abolitionists are the "anti-psychiatrists," who, somewhat surprisingly, count in their ranks a number of well-known psychiatrists. For them mental illness simply does not exist in the field of psychiatry (4). They reject entirely the medical model of mental illness and insist that acceptance of it relies on a fiction accepted jointly by the state and by psychiatrists as a device for exerting social control over annoying or unconventional people. The anti-psychiatrists hold that these people ought to be afforded the dignity of being held responsible for their behavior and required to accept its consequences. In addition, some members of this group believe that the phenomena of "mental illness" often represent essentially a tortured protest against the insanities of an irrational society (5). They maintain that society should not be encouraged in its oppressive course by affixing a pejorative label to its victims.

Among the abolitionists are some civil liberties lawyers who both assert their passionate support of the magisterial importance of individual liberty and react with repugnance and impatience to what they see as the abuses of psychiatric practice in this field—the commitment of some individuals for flimsy and possibly self-serving reasons and their inhuman warehousing in penal institutions wrongly called "hospitals."

The abolitionists do not oppose psychiatric treatment when it is conducted with the agreement of those being treated. I have no doubt that they would try to gain the consent of the individuals described earlier to undergo treatment, including hospitalization. The psychiatrists in this group would be very likely to confine their treatment methods to psychotherapeutic efforts to influence the aberrant behavior. They would be unlikely to use drugs and would certainly eschew such somatic therapies as ECT. If efforts to enlist voluntary compliance with treatment failed, the abolitionists would not employ any means of coercion. Instead, they would step aside and allow social, legal, and community sanctions to take their course. If a human being should be jailed or a human life lost as a result of this attitude, they would accept it as a necessary evil to be tolerated in order to avoid the greater evil of unjustified loss of liberty for others (6).

THE MEDICAL MODEL PSYCHIATRISTS

I use this admittedly awkward and not entirely accurate label to designate the position of a substantial number of psychiatrists. They believe that mental illness is a meaningful concept and that under certain conditions its existence justifies the state's exercise, under the doctrine of parens patriae, of its right and obligation to arrange for the hospitalization of the sick individual even though coercion is involved and he is deprived of his liberty. I believe that these psychiatrists would recommend involuntary hospitalization for all six of the patients described earlier.

The Medical Model

There was a time, before they were considered to be ill, when individuals who displayed the kind of behavior I described earlier were put in "ships of fools" to wander the seas or were left to the mercies, sometimes tender but often savage, of uncomprehending communities that regarded them as either possessed or bad. During the Enlightenment and the early nineteenth century, however, these individuals gradually came to be regarded as sick people to be included under the humane and caring umbrella of the Judeo-Christian attitude toward illness. This attitude, which may have reached its height during the era of moral treatment in the early nineteenth century, has had unexpected and ambiguous consequences. It became overextended and partially perverted, and these excesses led to the reaction that is so strong a current in today's attitude toward mental illness.

However, reaction itself can go too far, and I believe that this is already happening. Witness the disastrous consequences of the precipitate dehospitalization that is occurring all over the country. To remove the protective mantle of illness from these disturbed people is to expose them, their families, and their communities to consequences that are certainly maladaptive and possibly irreparable. Are we really acting in accordance with their best interests when we allow them to "die with their rights on" (1) or when we condemn

them to a "preservation of liberty which is actually so destructive as to constitute another form of imprisonment" (7)? Will they not suffer "if [a] liberty they cannot enjoy is made superior to a health that must sometimes be forced on them" (8)?

Many of those who reject the medical model out of hand as inapplicable to so-called "mental illness" have tended to oversimplify its meaning and have, in fact, equated it almost entirely with organic disease. It is necessary to recognize that it is a complex concept and that there is a lack of agreement about its meaning. Sophisticated definitions of the medical model do not require only the demonstration of unequivocal organic pathology. A broader formulation, put forward by sociologists and deriving largely from Talcott Parsons' description of the sick role (9), extends the domain of illness to encompass certain forms of social deviance as well as biological disorders. According to this definition, the medical model is characterized not only by organicity but also by being negatively valued by society, by "nonvoluntariness," thus exempting its exemplars from blame, and by the understanding that physicians are the technically competent experts to deal with its effects (10).

Except for the question of organic disease, the patients I described earlier conform well to this broader conception of the medical model. They are all suffering both emotionally and physically, they are incapable by an effort of will of stopping or changing their destructive behavior, and those around them consider them to be in an undesirable sick state and to require medical attention.

Categorizing the behavior of these patients as involuntary may be criticized as evidence of an intolerably paternalistic and antitherapeutic attitude that fosters the very failure to take responsibility for their lives and behavior that the therapist should uncover rather than encourage. However, it must also be acknowledged that these severely ill people are not capable at a conscious level of deciding what is best for themselves and that in order to help them examine their behavior and motivation, it is necessary that they be alive and available for treatment. Their verbal message that they will not accept treatment may at the same time be conveying other more covert messages—that they are desperate and want help even though they cannot ask for it (11).

Although organic pathology may not be the only determinant of the medical model, it is of course an important one and it should not be avoided in any discussion of mental illness. There would be no question that the previously described patient with delirium tremens is suffering from a toxic form of brain disease. There are a significant number of other patients who require involuntary hospitalization because of organic brain syndrome due to various causes. Among those who are not overtly organically ill, most of the candidates for involuntary hospitalization suffer from schizophrenia or one of the major affective disorders. A growing and increasingly impressive body of evidence points to the presence of an important genetic-biological factor in these conditions; thus, many of them qualify on these grounds as illnesses.

Despite the revisionist efforts of the anti-psychiatrists, mental illness *does* exist. It does not by any means include all of the people being treated by psychiatrists (or by nonpsychiatrist physicians), but it does encompass those few desperately sick people for whom involuntary commitment must be considered. In the words of a recent article, "The problem is that mental illness is not a myth. It is not some palpable falsehood propagated among the populace by power-mad psychiatrists, but a cruel and bitter reality that has been with the human race since antiquity" (12, p.1483).

Criteria for Involuntary Hospitalization

Procedures for involuntary hospitalization should be instituted for individuals who require care and treatment because of diagnosable mental illness that produces symptoms, including marked impairment in judgment, that disrupt their intrapsychic and interpersonal functioning. All three of these criteria must be met before involuntary hospitalization can be instituted.

1. *Mental illness*. This concept has already been discussed, but it should be repeated that only a belief in the existence of illness justifies involuntary commitment. It is a fundamental assumption that makes aberrant behavior a medical matter and its care the concern of physicians.

2. *Disruption of functioning*. This involves combinations of serious and often obvious disturbances that are both intrapsychic (for example, the suffering of severe depression) and interpersonal (for example, withdrawal from others because of depression). It does not include minor peccadilloes or eccentricities. Furthermore, the behavior in question must represent symptoms of the mental illness from which the patient is suffering. Among these symptoms are actions that are imminently or potentially dangerous in a physical sense to self or others, as well as other manifestations of mental illness such as those in the cases I have described. This is not to ignore dangerousness as a criterion for commitment but rather to put it in its proper place as one of a number of symptoms of the illness. A further manifestation of the illness, and indeed, the one that makes involuntary rather than voluntary hospitalization necessary, is impairment of the patient's judgment to such a degree that he is unable to consider his condition and make decisions about it in his own interests.

3. *Need for care and treatment*. The goal of physicians is to treat and cure their patients; however, sometimes they can only ameliorate the suffering of their patients and sometimes all they can offer is care. It is not possible to predict whether someone will respond to treatment; nevertheless, the need for treatment and the availability of facilities to carry it out constitute essential preconditions that must be met to justify requir-

ing anyone to give up his freedom. If mental hospital patients have a right to treatment, then psychiatrists have a right to ask for treatability as a front-door as well as a back-door criterion for commitment (7). All of the six individuals I described earlier could have been treated with a reasonable expectation of returning to a more normal state of functioning.

I believe that the objections to this formulation can be summarized as follows.

1. The whole structure founders for those who maintain that mental illness is a fiction.

2. These criteria are also untenable to those who hold liberty to be such a supreme value that the presence of mental illness per se does not constitute justification for depriving an individual of his freedom; only when such illness is manifested by clearly dangerous behavior may commitment be considered. For reasons to be discussed later, I agree with those psychiatrists (13, 14) who do not believe that dangerousness should be elevated to primacy above other manifestations of mental illness as a sine qua non for involuntary hospitalization.

3. The medical model criteria are "soft" and subjective and depend on the fallible judgment of psychiatrists. This is a valid objection. There is no reliable blood test for schizophrenia and no method for injecting grey cells into psychiatrists. A relatively small number of cases will always fall within a grey area that will be difficult to judge. In those extreme cases in which the question of commitment arises, competent and ethical psychiatrists should be able to use these criteria without doing violence to individual liberties and with the expectation of good results. Furthermore, the possible "fuzziness" of some aspects of the medical model approach is certainly no greater than that of the supposedly "objective" criteria for dangerousness, and there is little reason to believe that lawyers and judges are any less fallible than psychiatrists.

4. Commitment procedures in the hands of psychiatrists are subject to intolerable abuses. Here, as Peszke said, "It is imperative that we differentiate between the principle of the process of civil commitment and the practice itself" (13, p. 825). Abuses can contaminate both the medical and the dangerousness approaches, and I believe that the abuses stemming from the abolitionist view of no commitment at all are even greater. Measures to abate abuses of the medical approach include judicial review and the abandonment of indeterminate commitment. In the course of commitment proceedings and thereafter, patients should have access to competent and compassionate legal counsel. However, this latter safeguard may itself be subject to abuse if the legal counsel acts solely in the adversary tradition and undertakes to carry out the patient's wishes even when they may be destructive.

Comment

The criteria and procedures outlined will apply most appropriately to initial episodes and recurrent attacks of mental illness. To put it simply, it is necessary to find a way to satisfy legal and humanitarian considerations and yet allow psychiatrists access to initially or acutely ill patients in order to do the best they can for them. However, there are some involuntary patients who have received adequate and active treatment but have not responded satisfactorily. An irreducible minimum of such cases, principally among those with brain disorders and process schizophrenia, will not improve sufficiently to be able to adapt to even a tolerant society.

The decision of what to do at this point is not an easy one, and it should certainly not be in the hands of psychiatrists alone. With some justification they can state that they have been given the thankless job of caring, often with inadequate facilities, for badly damaged people and that they are now being subjected to criticism for keeping these patients locked up. No one really knows what to do with these patients. It may be that when treatment has failed they exchange their sick role for what has been called the impaired role (15), which implies a permanent negative evaluation of them coupled with a somewhat less benign societal attitude. At this point, perhaps a case can be made for giving greater importance to the criteria for dangerousness and releasing such patients if they do not pose a threat to others. However, I do not believe that the release into the community of these severely malfunctioning individuals will serve their interests even though it may satisfy formal notions of right and wrong.

It should be emphasized that the number of individuals for whom involuntary commitment must be considered is small (although, under the influence of current pressures, it may be smaller than it should be). Even severe mental illness can often be handled by securing the cooperation of the patient, and certainly one of the favorable effects of the current ferment has been to encourage such efforts. However, the distinction between voluntary and involuntary hospitalization is sometimes more formal than meaningful. How "voluntary" are the actions of an individual who is being buffeted by the threats, entreaties, and tears of his family?

I believe, however, that we are at a point (at least in some jurisdictions) where, having rebounded from an era in which involuntary commitment was too easy and employed too often, we are now entering one in which it is becoming very difficult to commit anyone, even in urgent cases. Faced with the moral obloquy that has come to pervade the atmosphere in which the decision to involuntarily hospitalize is considered, some psychiatrists, especially younger ones, have become, as Stone (16) put it, "soft as grapes" when faced with the prospect of committing anyone under any circumstances.

THE CIVIL LIBERTIES LAWYERS

I use this admittedly inexact label to designate those members of the legal profession who do not in prin-

ciple reject the necessity for involuntary hospitalization but who do reject or wish to diminish the importance of medical model criteria in the hands of psychiatrists. Accordingly, the civil liberties lawyers, in dealing with the problem of involuntary hospitalization, have enlisted themselves under the standard of dangerousness, which they hold to be more objective and capable of being dealt with in a sounder evidentiary manner than the medical model criteria. For them the question is not whether mental illness, even of disabling degree, is present, but only whether it has resulted in the probability of behavior dangerous to others or to self. Thus they would scrutinize the cases previously described for evidence of such dangerousness and would make the decision about involuntary hospitalization accordingly. They would probably feel that commitment is not indicated in most of these cases, since they were selected as illustrative of severe mental illness in which outstanding evidence of physical dangerousness was not present.

The dangerousness standard is being used increasingly not only to supplement criteria for mental illness but, in fact, to replace them entirely. The recent Supreme Court decision in *O'Connor v. Donaldson* (17) is certainly a long step in this direction. In addition, "dangerousness" is increasingly being understood to refer to the probability that the individual will inflict harm on himself or others in a specific physical manner rather than in other ways. This tendency has perhaps been carried to its ultimate in the *Lessard v. Schmidt* case (18) in Wisconsin, which restricted suitability for commitment to the "extreme likelihood that if the person is not confined, he will do immediate harm to himself or others." (This decision was set aside by the U.S. Supreme Court in 1974.) In a recent Washington, D.C., Superior Court case (19) the instructions to the jury stated that the government must prove that the defendant was likely to cause "substantial physical harm to himself or others in the reasonably foreseeable future."

For the following reasons, the dangerousness standard is an inappropriate and dangerous indicator to use in judging the conditions under which someone should be involuntarily hospitalized. Dangerousness is being taken out of its proper context as one among other symptoms of the presence of severe mental illness that should be the determining factor.

1. To concentrate on dangerousness (especially to others) as the sole criterion for involuntary hospitalization deprives many mentally ill persons of the protection and treatment that they urgently require. A psychiatrist under the constraints of the dangerousness rule, faced with an out-of-control manic individual whose frantic behavior the psychiatrist truly believes to be a disguised call for help, would have to say, "Sorry, I would like to help you but I can't because you haven't threatened anybody and you are not suicidal." Since psychiatrists are admittedly not very good at accurately predicting dangerousness to others, the evidentiary standards for commitment will be very stringent. This will result in mental hospitals becoming prisons for a small population of volatile, highly assaultive, and untreatable patients (14).

2. The attempt to differentiate rigidly (especially in regard to danger to self) between physical and other kinds of self-destructive behavior is artificial, unrealistic, and unworkable. It will tend to confront psychiatrists who want to help their patients with the same kind of dilemma they were faced with when justification for therapeutic abortion on psychiatric grounds depended on evidence of suicidal intent. The advocates of the dangerousness standard seem to be more comfortable with and pay more attention to the factor of dangerousness to others even though it is a much less frequent and much less significant consequence of mental illness than is danger to self.

3. The emphasis on dangerousness (again, especially to others) is a real obstacle to the right-to-treatment movement since it prevents the hospitalization and therefore the treatment of the population most amenable to various kinds of therapy.

4. Emphasis on the criterion of dangerousness to others moves involuntary commitment from a civil to a criminal procedure, thus, as Stone (14) put it, imposing the procedures of one terrible system on another. Involuntary commitment on these grounds becomes a form of preventive detention and makes the psychiatrist a kind of glorified policeman.

5. Emphasis on dangerousness rather than mental disability and helplessness will hasten the process of deinstitutionalization. Recent reports (20, 21) have shown that these patients are not being rehabilitated and reintegrated into the community, but rather, that the burden of custodialism has been shifted from the hospital to the community.

6. As previously mentioned, emphasis on the dangerousness criterion may be a tactic of some of the abolitionists among the civil liberties lawyers (22) to end involuntary hospitalization by reducing it to an unworkable absurdity.

DISCUSSION

It is obvious that it is good to be at liberty and that it is good to be free from the consequences of disabling and dehumanizing illness. Sometimes these two values are incompatible, and in the heat of the passions that are often aroused by opposing views of right and wrong, the partisans of each view may tend to minimize the importance of the other. Both sides can present their horror stories—the psychiatrists, their dead victims of the failure of the involuntary hospitalization process, and the lawyers, their Donaldsons. There is a real danger that instead of acknowledging the difficulty of the problem, the two camps will become polarized, with a consequent rush toward extreme and untenable solutions rather than working toward reasonable ones.

The path taken by those whom I have labeled the

abolitionists is an example of the barren results that ensue when an absolute solution is imposed on a complex problem. There are human beings who will suffer greatly if the abolitionists succeed in elevating an abstract principle into an unbreakable law with no exceptions. I find myself oppressed and repelled by their position, which seems to stem from an ideological rigidity which ignores that element of the contingent immanent in the structure of human existence. It is devoid of compassion.

The positions of those who espouse the medical model and the dangerousness approaches to commitment are, one hopes, not completely irreconcilable. To some extent these differences are a result of the vantage points from which lawyers and psychiatrists view mental illness and commitment. The lawyers see and are concerned with the failures and abuses of the process. Furthermore, as a result of their training, they tend to apply principles to classes of people rather than to take each instance as unique. The psychiatrists, on the other hand, are required to deal practically with the singular needs of individuals. They approach the problem from a clinical rather than a deductive stance. As physicians, they want to be in a position to take care of and to help suffering people whom they regard as sick patients. They sometimes become impatient with the rules that prevent them from doing this.

I believe we are now witnessing a pendular swing in which the rights of the mentally ill to be treated and protected are being set aside in the rush to give them their freedom at whatever cost. But is freedom defined only by the absence of external constraints? Internal physiological or psychological processes can contribute to a throttling of the spirit that is as painful as any applied from the outside. The "wild" manic individual without his lithium, the panicky hallucinator without his injection of fluphenazine hydrochloride and the understanding support of a concerned staff, the sodden alcoholic—are they free? Sometimes, as Woody Guthrie said, "Freedom means no place to go."

Today the civil liberties lawyers are in the ascendancy and the psychiatrists on the defensive to a degree that is harmful to individual needs and the public welfare. Redress and a more balanced position will not come from further extension of the dangerousness doctrine. I favor a return to the use of medical criteria by psychiatrists—psychiatrists, however, who have been chastened by the buffeting they have received and are quite willing to go along with even strict legal safeguards as long as they are constructive and not tyrannical.

Drug and Psychotherapy Interactions in Depression

BY LINO COVI, M.D., RONALD S. LIPMAN, PH.D., RENATO D. ALARCON, M.D., AND VIRGINIA K. SMITH

The authors conducted a series of multiple regression analyses of data from depressed patients. They found that 8 factors consistently predicted treatment response: a lower initial level of distress, imipramine treatment, a positive attitude toward group psychotherapy, and a good employment history predicted lower posttreatment distress levels; estrogen maintenance treatment was related to better response to diazepam, and a low level of intelligence predicted better response to both diazepam and imipramine; and a low initial level of interpersonal sensitivity and a significant other's having an unfavorable attitude toward psychiatric treatment were associated with better response to group psychotherapy.

ONE OF THE MOST VALUABLE contributions that clinical research can make to the practice of psychiatry is to add to the repertoire of possible predictors of response to treatment.

The prevalence of depressive illness is quite high. Klerman (1) maintained that 10% of the population of the United States will have an episode of clinical depression at some time in their lives. This high incidence of depression will be reflected in the proportion of depressive patients to patients with other illnesses being treated by clinicians. An increased ability to choose the right treatment for the right patient is therefore a particularly important contribution to public health. Current clinical psychiatric practice tends to prefer the combination of pharmacotherapy and psychotherapy in the treatment of depression in outpatient settings. The differential indications for psychotherapy and pharmacotherapy and their combinations have been insufficiently studied (2). This report presents some experimental data bearing on the prediction of response to six types of treatment of depression in a homogeneous patient population.

The following combinations were studied: 1) group psychotherapy with placebo, 2) minimal supportive psychotherapy with placebo, 3) imipramine in combination with group therapy, 4) imipramine in combination with minimal supportive psychotherapy, 5) diazepam in combination with group psychotherapy, and 6) diazepam in combination with minimal supportive psychotherapy. The study sample consisted of women who ranged in age from 20 to 50, who were nonpsychotic, and who had a depression severity score of at least 7 on the Raskin Depression Screen (3).

The study was conducted in the outpatient departments of the Phipps Psychiatric Clinic of Johns Hopkins Hospital in East Baltimore and the Gundry Hospital in West Baltimore. Two experienced psychiatrists (Joseph H. Pattison, M.D., and James E. Smith III, M.D.) treated all of the psychiatric patients at both clinics. Written informed consent was obtained from the patients included in the study. After a 2-week placebo washout period, the patients were randomly assigned to one of the six types of treatment described above for a 16-week active treatment period. Further details of the design and techniques used in the study have been described elsewhere (4, 5).

Three groups of individuals provided improvement ratings: 1) the patients completed two self-rating scales, the Hopkins Symptom Check List (HSCL) (5) and the Profiles of Mood State (POMS) (5); 2) the treating psychiatrist rated improvement using global mood scales derived from the POMS; and 3) a person significant to the patient provided global improvement ratings and ratings of the quality of his relationship with the patient on the Barrett-Lennard Relationship Inventory (RI) (6). The implications of using a significant other person's ratings in research have been reported elsewhere (7).

Other data obtained to provide possible predictors of improvement included such demographic information about the patient as age, marital status, and education; physician ratings, such as the Brief Psychiatric Rating Scale (BPRS) (8); chronicity of the patient's illness; and the patient's medication history. The patient also rated the treating physician on the RI, and a social worker who interviewed the significant other person rated that person's views toward psychiatric treatment.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration grant MH-15720 from the National Institute of Mental Health.

The authors wish to thank Ms. Margaret B. Winogrodzki for technical assistance and Joseph H. Pattison, M.D., and James E. Smith III, M.D., who treated the patients studied.

METHOD

Three hundred forty-six patients were screened for the study; 279 of these were accepted for treatment, and 218 completed the placebo washout period and entered the active phase. Two hundred twelve of these 218 patients returned for at least two visits after beginning active medication. One hundred forty-nine patients completed the entire 16-week active treatment phase with reasonable compliance to study procedures.

The typical patient was married (71% of the 149 patients who completed the study), was Protestant (50%), worked as a housewife (60%), was in Hollingshead's social class IV (9) (39%), and had had at least one previous depressive episode (60%). Most of the patients were chronically ill. The mean length of their present illness was 41 weeks; the median was 25 weeks. Covariance analyses, using a 2×3×2 design (therapy×medication×clinic), revealed a general and strong superiority of imipramine over diazepam[1] and placebo according to doctors' and patients' ratings of symptoms and mood. These findings have been reported in detail elsewhere (4, 5).

For the present analyses we used 22 potential predictors of improvement selected on the basis of previous research findings and/or from hypotheses developed on the basis of clinical experience. This approach provided a further test of the consistency of the results of the previous covariance analyses (4, 5).[2]

The 22 predictors are as follows:

1. The initial level of distress indicated on each of the measures of improvement. This predictor has often proven to be the single most powerful predictor of outcome (10).
2. Type of psychotherapy, i.e., group psychotherapy versus minimal supportive psychotherapy.
3. Drugs, i.e., imipramine, diazepam, or placebo.
4. Age as a continuous variable (3).
5. Marital status, i.e., never married, currently married, or formerly married (3).
6. Occupation, grouped into the seven categories described by Hollingshead (9).
7. Social class, using the five classes of the Hollingshead classification (9). Variables 6 and 7 were found by Downing and associates (11) to be predictive of drug treatment response.
8. Chronicity in terms of duration of present illness in weeks, which in psychotherapy studies has predicted outcome (12).
9. Peak of illness according to a 7-point rating designed to reflect when the worst point of distress occurred, from less than 1 week to 1 year or more before entering the study.
10. The patient's attitude toward assignment to group psychotherapy, as judged by the physicians who interviewed the patient before the study began on a 5-point scale, from very eager to very reluctant.
11. Concurrent treatment with an estrogen type of medication, either as part of an oral contraceptive regimen or as part of a postmenopausal replacement treatment. (Surprisingly, estrogen treatment showed a high level of significance in interaction with medication, i.e., in enhancing the therapeutic effect of diazepam, in several multivariate covariance analyses in this study).
12. Clinical setting, whether at Phipps Psychiatric Clinic or Gundry Hospital.
13. The level of distress noted by the patient on the interpersonal sensitivity factor of the HSCL before beginning active treatment. The 7 items included in this factor are as follows: feeling critical of others, feeling easily annoyed or irritated, having temper outbursts you could not control, your feelings being easily hurt, feeling others do not understand you or are unsympathetic, feeling that people are unfriendly or dislike you, and feeling inferior to others. This factor was felt to describe personality characteristics common to individuals who tend to adjust poorly to group interactions.
14. The four types of depression described by Overall and Hollister (13), i.e., anxious, hostile, retarded, and agitated, as determined by computer assignment on the basis of the BPRS rating given by the intake physicians. Overall and Hollister reported interactions between tranquilizers and antidepressant medications and these types of depression.
15. The attitude toward psychiatric treatment expressed by the significant other person in the patient's life as rated by a social worker after an interview with this person. On the basis of clinical impression, it was felt that a favorable attitude of the family of the patient toward psychiatric treatment would facilitate the patient's response to treatment.
16. The attitude of the patient toward the treating physician as measured by the total score derived from the RI. A previous study (14), in which two of us participated (L.C. and R.S.L.), showed that a positive relationship between the patient and the physician predicted a favorable treatment outcome.
17. An endogenomorphic score developed to conform with Donald Klein's theory of differential drug response in endogenomorphic and nonendogenomorphic depression (15). It should be noted that Klein's theory of differential drug response also included neurotic and reactive subtypes that were not really measured by the endogenomorphic dimension.
18. An endogenomorphic score similar to the one used for predictor 17 but derived from the patient's self-rating.
19. The employment history of the patient categorized into the four classes of good, fair, poor, and none.
20. The patient's intelligence as judged by the treat-

[1]The dosage for imipramine ranged from 100 to 200 mg a day (average=125 mg a day). The dosage for diazepam ranged from 10 to 20 mg a day (average=12.5 mg a day).

[2]Multiple regression analysis permits a statistical test of the individual effect of each variable in the predictor equation by adjusting the score of each item in the equation for the effect of all other items in the equation.

ing physician on the first visit and classified on a 7-point scale, from much above average to much below average.

21. The attitude of the patient toward the study medications as determined by the treating physician on the first visit on a 7-point scale, ranging from markedly positive to markedly negative.

22. The patient's attitude toward group therapy as determined by the treating physician on the first visit on a 7-point scale, ranging from markedly positive to markedly negative. Variables 19, 20, and 22 were found to be predictive of treatment outcome by Downing and associates (11).

The predictor pool, consisting of these 22 predictors and their interactions with type of medication and with type of therapy, was searched, using a stepwise multiple regression approach (16), to determine the variables or combination of variables that most reliably predicted improvement for each of the improvement criteria in the three areas of depression, anxiety, and global improvement.

The statistical program used for the multiple regression analyses included only patients who had no missing data. In this regard, the patient sample of 212 comprised the 149 patients who completed the full 16 weeks of the study with reasonable adherence to protocol plus an additional 63 patients who completed at least 2 weeks of the study with adherence to protocol. These 212 patients represented the data base for potential analyses. In the case of the 63 patients who did not complete the full study (on average, these patients completed 11 weeks of the study), their scores on their last visits were used in the end-point analysis reported here. Their last valid visit scores were treated as equivalent to the 16th-week scores of the patients who completed the 16 weeks of treatment. An average of 179 patients entered into the multiple regression analysis.

The attrition in patients was entirely due to missing data, which included data missing on the following variables: 1) age (2 missing), 2) marital status (2 missing), 3) occupation (3 missing), 4) social class (2 missing), 5) attitude toward psychotherapy (5 missing), 6) HSCL interpersonal sensitivity factor score at week 3 (1 missing), and 7) attitude of the significant other toward psychiatric treatment (13 missing).

RESULTS

Eight measures were found to be highly consistent predictors of outcome, i.e., they were significantly related to outcome in at least one-third of the predictor analyses (see tables 1–3). These 8 predictors include 4 variables that predicted outcome regardless of treatment assignment, 2 that predicted outcome in com-

* The predictors were studied alone (main effects), in combination with type of medication (drug interactions), and in combination with type of therapy (therapy interactions).

bination with drug assignment, and 2 that predicted outcome in combination with therapy assignment.

The general predictors of outcome are as follows: predictor 1, initial level of distress (a low initial level of distress correlated with good outcome); predictor 3, drug assignment (patients who received imipramine improved substantially more than patients who received diazepam or placebo, and those who received diazepam or placebo did not reliably differ from each other); predictor 19, employment history (poor employment history before entering the study predicted less improvement than did good, fair, or no employment history); and predictor 22, the patient's attitude toward group psychotherapy (a positive attitude toward group psychotherapy predicted better outcome). A representative sample of means for these main effect predictors is presented in table 4.

The predictors that interacted with type of medication (see figures 1 and 2) were as follows: predictor 11, concurrent treatment with an estrogen type of medication, which was related to a better response to diazepam; and predictor 20, intelligence (a lower level of intelligence predicted a relatively better response to both imipramine and diazepam).

The predictors that interacted with type of therapy (see figures 3 and 4) were as follows: predictor 13, initial level of distress on interpersonal sensitivity (patients who had lower scores felt less critical of others, less inferior to others, etc., and did relatively better in group psychotherapy than in minimal supportive psychotherapy); predictor 15, attitude toward psychiatric treatment expressed by the significant other person in the patient's life as rated by a social worker (a relatively less positive attitude toward treatment predicted that the patient would do better in group psychotherapy than in minimal supportive therapy).

DISCUSSION

Given the present state of the art of psychiatric treatment, the clinician's decision to assign depressed patients to psychotherapy and/or pharmacotherapy is largely dependent on clinical intuition. Although covar-

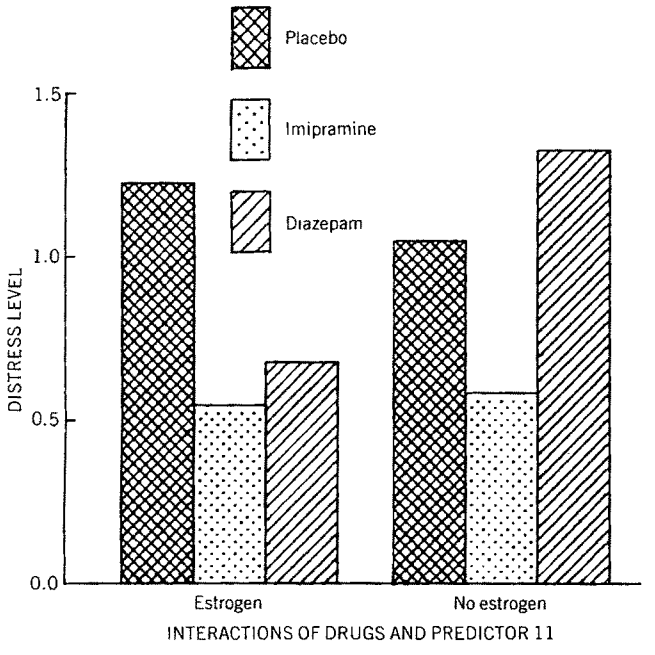
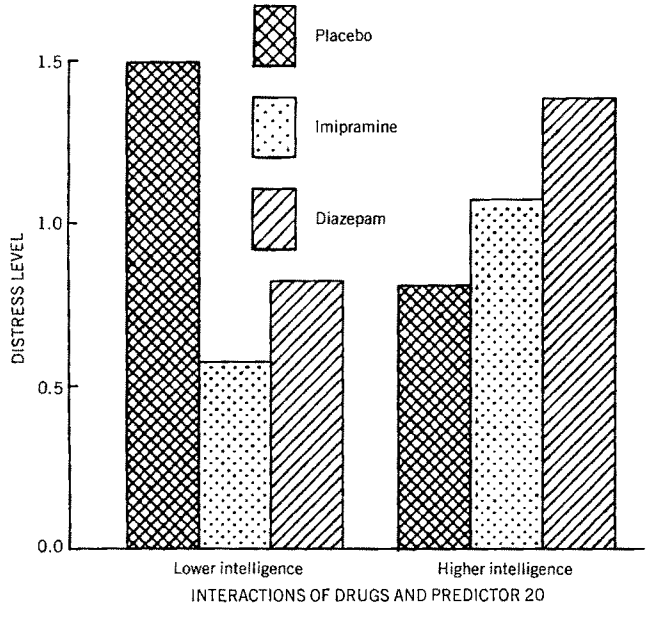
iance analyses of controlled studies typically give important information concerning the relative efficacy of various drugs and psychotherapies, the more complex problem of sorting out the relative contributions of the many noncontrolled factors that can influence treatment outcome is better served by stepwise multiple regression analyses.

We have attempted to be conservative in interpreting the results of our study by stressing only the consistent predictors of response that showed a high level of significance and that were found reliably related to outcome in more than one-third of the analyses performed. Furthermore, these predictors were selected on the basis of findings from previous studies or on the basis of extensive clinical experience. We therefore feel that some of the more serious objections to

FIGURE 1
Representative Sample of Effects of Interactions of Drugs and Predictor 11 on Patients' Adjusted Mean Distress Levels





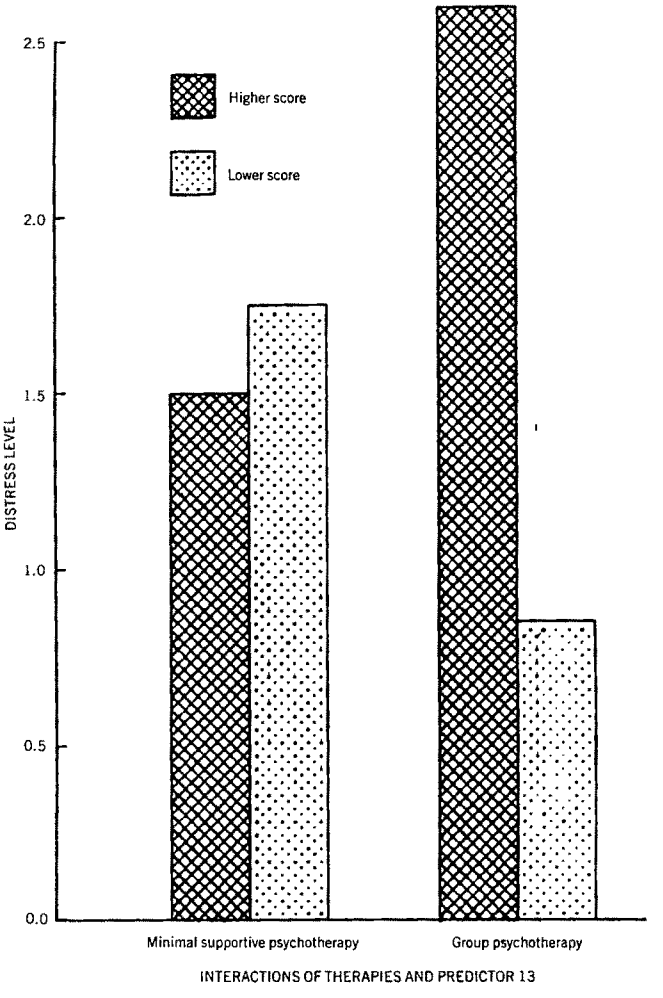


FIGURE 2
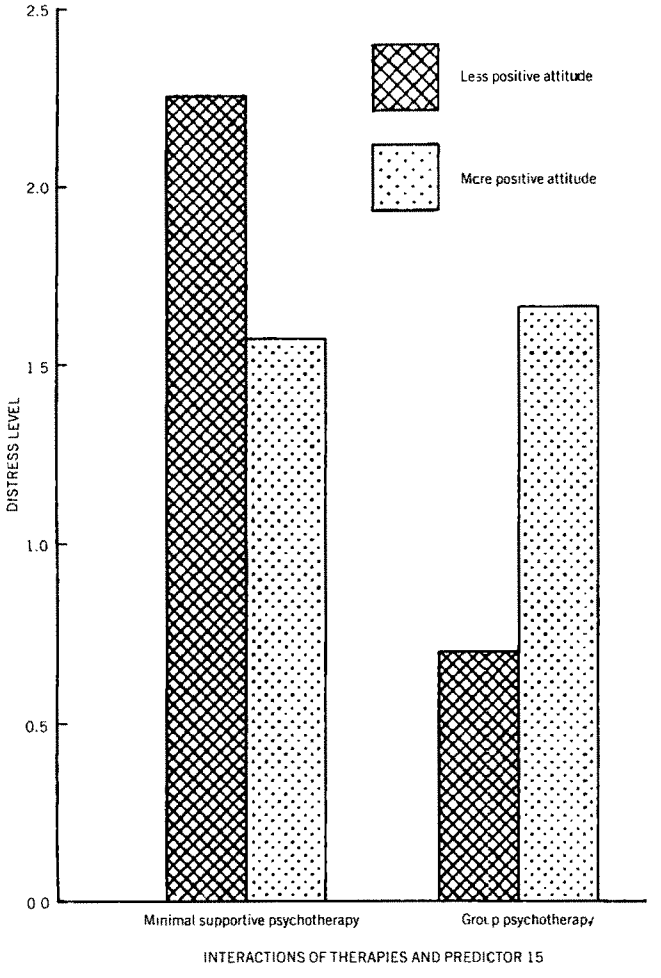
Representative Sample of Effects of Interactions of Drugs and Predictor 20 on Patients' Adjusted Mean Distress Levels

our statistical approach (17) have been minimized.



What practical implications can the clinician draw from this study? He can expect to see the most improvement in depression and anxiety by the end of 16 weeks of treatment among female patients who were most distressed at the onset of treatment and those who were initially favorably disposed toward more intensive psychotherapy, including group psychotherapy. On the other hand, female patients with a poor employment history would be expected to show relatively less improvement than those with a good employment history by the end of 16 weeks of treatment. He can count on reliably better results with imipramine than with diazepam or placebo, with either group or minimal supportive psychotherapy. On the other hand, our data suggest that female patients receiving estrogen hormones may respond quite well to diazepam. Patients who the clinican feels are less intelligent than average may do relatively better on active medication than patients he considers above average in intelligence, but the latter group may improve relatively more on treatment with inert medication.

FIGURE 3
Representative Sample of Effects of Interactions of Therapies and Predictor 13 on Patients' Adjusted Mean Distress Levels

The person who is easily hurt, who feels critical of others, and who is easily irritated should be expected to do less well in group therapy. On the other hand, if those who are important to a female patient are not favorably disposed toward psychiatric treatment, group therapy may well be the treatment of choice.

FIGURE 4
Representative Sample of Effects of Interactions of Therapies and Predictor 15 (Attitude of Significant Other) on Patients' Adjusted Mean Distress Levels

COMMENT

Despite our care in selecting consistent predictors, the results of the kind of multiple regression analyses presented in this paper are often difficult to replicate in independent samples. Until such replication is available, these findings should be considered tentative.

For instance, contrary to other, similar studies, our study has shown few demographic factors to be predictive of treatment response; this difference may be due to the homogeneity of our population, which was limited to white women between the ages of 20 and 50 years. It should also be noted that our predictor analyses were based on 16 weeks of treatment, in contrast to most other predictor studies, which employed much shorter treatment periods.

The finding of a positive therapeutic interaction between estrogen and diazepam is a most tentative finding, but it is suggestive of a possible direction for further investigation. In this regard, our initial expectation was that imipramine would be more influenced than diazepam by the presence or absence of estrogen (18). We would further caution that only a small number of patients (15 per medication), not randomly assigned, and on a variety of estrogen-containing medications of varying dosages of estrogen, were grouped together for analytic purposes. Further research is therefore needed to more clearly test the validity of this clinically important potential drug interaction.

Short Versus Long Hospitalization: A Prospective Controlled Study. IV. One-Year Follow-Up Results for Schizophrenic Patients

BY IRA D. GLICK, M.D., WILLIAM A. HARGREAVES, PH.D., JOAN DRUES, M.A., AND JONATHAN A. SHOWSTACK

The authors compared treatment results for 141 schizophrenic patients randomly assigned to short-term or long-term hospitalization. Test results indicated that the long-term group was functioning significantly better one year after admission according to global measures only. The authors caution that the differences between the two groups, although statistically reliable, were modest and may have been confounded by the amount of psychotherapy the patients received after hospitalization. Although there appears to be a general advantage to the long-term approach, further work will be needed to identify patient subgroups for whom this more expensive treatment is cost effective.

THIS STUDY WAS DESIGNED to determine the relative effectiveness of short-term hospitalization (i.e., 21–28 days) compared with long-term hospitalization (i.e., 90–120 days) for schizophrenic patients in need of hospital care for whom both types of treatment are judged clinically feasible. We have previously reported limited preliminary results (1) and complete results (2, 3) of the inpatient phase of this study of a group of schizophrenic patients and an additional group of nonschizophrenic patients. This paper reports the results of a one-year follow-up of our study group of 141 schizophrenic patients; the next paper in this series, which follows in this issue of the *Journal*, reports on our group of 74 nonschizophrenic patients.

There have been virtually no controlled evaluations of alternative methods of in-hospital treatment for acute schizophrenic episodes, such as brief hospital stay versus more extended stay. Treatment approaches that involve longer hospitalization are being discarded even though there is very little evidence about the effect this has on the lives of patients.

We have discussed elsewhere (1) the few studies that have some relevance to this question. Two additional studies have since come to our attention. Smith and associates (4), using a nonrandomized design, compared outcomes of first hospital admissions to a regional community mental health center (which involved a mean of 47 days of hospitalization) with those of patients given traditional state hospital care (which involved a mean of 137 days of hospitalization). Most of the patients they studied were diagnosed as having personality disorder (64%), 18% were diagnosed as neurotic, and 13% as psychotic. Smith and associates reported that over a four-year follow-up period,

> The [community mental health] center group had fewer days hospitalized, less disability, less total cost per patient and per capita, as well as a lower cost-benefit ratio than traditional state hospitals. Neither system of care, however, was successful with a small hard-core group of long-term patients.

Schooler and associates (5), reporting on the patients studied by the National Institute of Mental Health-Psychopharmacology Service Center (NIMH-PSC) collaborative study group, found that patients who received placebo while hospitalized stayed in the hospital an average of 6 weeks longer than patients who received phenothiazines but were less likely to be rehospitalized. In this study as well as in that of Smith and associates (4) the length of hospital stay was confounded with other variables, preventing any confident conclusions about length of stay.

METHOD

The inpatient phase of our study was conducted on the Clinical Research Ward of the Langley Porter Institute. This is a coed ward with a 26-patient capacity, operated as an open door unit that can accept only voluntary admissions. Patients' fees are adjusted according

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are all with the Clinical Research Ward, Langley Porter Institute, University of California, San Francisco, Calif. 94143. Dr. Glick is Associate Professor of Psychiatry in Residence, Dr. Hargreaves is Associate Professor of Medical Psychology in Residence, Ms. Drues is Staff Research Associate, and Mr. Showstack is Staff Research Associate II.

This study was supported by Alcohol, Drug Abuse, and Mental Health Administration grants MH-20593, MH-12450 (Career Teacher Award to Dr. Glick), and MH-36809 (Research Scientist Development Award to Dr. Hargreaves) from the National Institute of Mental Health, and by grant FR-00122 for computing services to the University of California, San Francisco, from the National Institutes of Health.

to their ability to pay. It has a high staff:patient ratio, as is usual at a university hospital (1).

Treatment Assignment

All of the patients consecutively admitted to the Clinical Research Ward during a 26-month period were randomly assigned to either short-term (21–28 days) or long-term (90–120 days) hospitalization. After the study was explained to the patients, all of them agreed to participate. However, some potential patients probably chose not to seek admission because the nature of the study was explained to the referring person at the time of the initial inquiry about admitting a patient. Patients remained in the long- or short-term group regardless of final diagnosis. This removed any temptation to bias the diagnostic process to obtain some favored treatment for a particular patient. Although the definitions of "short-term" and "long-term" were target lengths of stay for patients in the study, in practice these produced a very good separation in the distributions of actual lengths of stay in the two groups, as has been previously reported (2, 3).

Diagnosis

The clinical diagnosis for research purposes was made by the staff psychiatrist in charge of the ward and by a research psychiatrist (I.D.G.) after the patient had been examined and studied (usually at least 10 days after admission). After a diagnosis of schizophrenia was agreed on as the most appropriate diagnosis for the patient, both psychiatrists independently rated each patient using the Certainty of Diagnosis of Schizophrenia Form developed by Mosher (6). The results of this assessment indicate that there was no significant difference between the short-term and long-term groups in the certainty of diagnosis of schizophrenia (chi-square test). Ninety percent of those diagnosed as schizophrenic were rated as either "definitely" or "almost definitely" schizophrenic.

Treatment Program

Goals and strategies for the short-term and long-term groups have already been described (1), including our strategy to balance the use of medication (2). We also measured the actual frequency of various treatment activities for a sample of patients and found that, within limits, the treatment was qualitatively and quantitatively close to that prescribed. Our impression is that the quality of the treatment was at least as good as, if not better than, that in other comparable clinical settings. Patients' impressions of the treatment were also measured. There was no difference between the short-term and long-term groups in patients' ratings of the helpfulness of treatment (7).

Aftercare can affect subsequent functioning. For a variety of reasons, we chose to use existing community services rather than provide a controlled aftercare program. Because variations in posthospital treatment can confound the direct effect of short versus long inpatient stay on one-year outcomes, these effects will be examined in some of the analyses reported below.

Patients

Of the 141 schizophrenic patients studied, 71 were short-term and 70 were long-term. The schizophrenic patients fit the selection criteria used in the NIMH-PSC multihospital study of phenothiazines (8), except that we relaxed the criterion requiring that the patient spend 12 months in the community after any previous hospitalization. There were no significant differences between the long-term and short-term groups in regard to sex, marital status, race, or age (chi-square test or t test). Despite random assignment, t tests showed that the long-term group had more education (mean difference, one year, $p<.05$), a higher socioeconomic status (mean difference, .5 on a 5-point scale, $p<.01$), and better premorbid adjustment (mean difference, .8 on a 13-point scale, $p<.05$). These variables will therefore be examined for their relation to outcome.

At one-year follow-up we obtained nearly complete data for 132 of the original sample of 141 schizophrenic patients. Some items are missing for these patients. We had no data for 3 patients and only partial data (obtained from interviews with significant others) for 6 patients, 2 of whom had committed suicide. This low attrition rate, plus inspection of the characteristics of short-term and long-term dropouts, indicated that differential attrition did not reduce the comparability of the two treatment groups.

Measuring Instruments

Seven instruments were used to evaluate outcome one year after admission: 1) the Health-Sickness Rating Scale (HSRS) (9), 2) the Psychiatric Evaluation Form (PEF) (10), 3) the Katz Adjustment Scales (KAS) (11) for patients, 4) the KAS for patients' relatives, 5) a historical information form (HIF) based in part on the Brief Follow-Up Rating Form developed by Soskis (12), 6) the Patient's Self-Evaluation of Current Status Form (PSECS) (13), and 7) the Family Members' Evaluation of Current Status of Patient Form (FMECS) (13). Baseline measures on the first five were obtained at admission, and the last two call for direct before and after comparisons. These measurements were more fully described in previous publications (1, 2).

For the analyses reported in this paper we computed a summary score for the social and treatment history data that consisted of the sum of standard scores on six items: 1) ratings of overall functioning, 2) ratings of role functioning, 3) ratings of percent of time functioning, 4) number of months unemployed, 5) number of hospitalizations, and 6) total number of days hospitalized. These scores were standardized separately at admission and at one year, using the total group of 215 schizophrenic and nonschizophrenic patients. In interpreting this summary score of historical data one should keep in mind that admission ratings apply to the average social functioning of the patient during the two

years before admission, but the other global ratings (the HSRS and the PEF overall severity of illness item) apply to only the week before admission. This was probably responsible for the fact that the baseline summary score of historical data proved to be the best predictor of all three global ratings at one year.

RESULTS

Global Outcome

Global outcome was measured using the HSRS, the overall severity item of the PEF, and the summary score of historical data (see table 1). The initial analy-

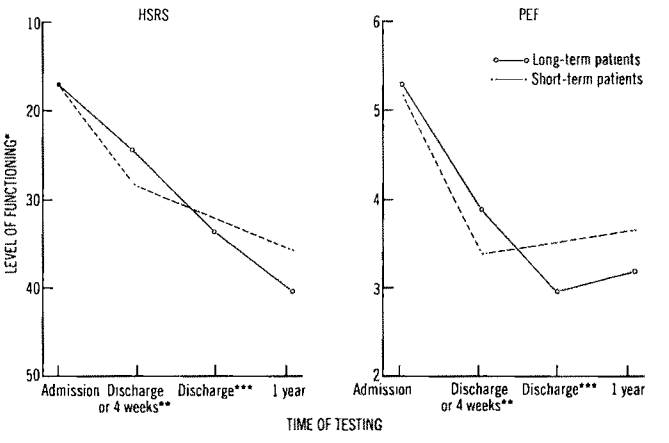
* Unless otherwise noted, a low score indicates better adjustment.
** A high score indicates better adjustment.
***There were missing data for a large number of patients on these items. The numbers of patients for whom data were available on the PEF mate role item were 15 short-term patients and 9 long-term patients. The respective numbers for the PEF parent role item were 16 and 8; for the PEF wage earner item, 15 and 16; for the PEF housekeeper item, 25 and 18; and for the PEF student trainee item, 14 and 12.

ses of these three variables employed a three-way analysis of covariance: treatment assignment (short versus long hospitalization) × sex × diagnosis (paranoid versus nonparanoid); the admission score on each variable was the covariate. Details of these three analyses are shown in table 2. Significant treatment assignment effects favoring the long-term patients were found on the HSRS and on the overall severity item of the PEF (see table 2). These two variables also showed a significant main effect for sex on these two variables, i.e., women were rated as showing greater improvement. Neither the diagnosis effect nor any of the interactions was significant for any of the three variables.

Inspection of these analyses show that the HSRS and PEF global scores had a restricted range at admission. The admission summary score of historical data, in contrast, showed a wider range because it applied to average functioning over a two-year preadmission period. We found that this score was the best predictor of all three global ratings at one year. We therefore repeated the analyses of covariance for the HSRS and the PEF overall severity item, using the admission summary score of historical data as the covariate.



This provided a better control of prehospital differences in functioning and tended to weaken the main effect of treatment assignment. The HSRS significance level changed from $p<.05$ to $p<.06$, and the PEF significance level changed from $p<.01$ to $p<.05$. We further examined the effect of adding, as covariates, the three

FIGURE 1
Mean Scores of Short-Term and Long-Term Schizophrenic Patients on the HSRS and the PEF Overall Severity of Illness Item

*A score of 50 on the HSRS indicates a better level of functioning; a score of 10 indicates a worse level. A score of 2 on the PEF overall severity item indicates a better level of functioning; a score of 6 indicates a worse level.
**The second time of testing for short-term patients took place at discharge; for the long-term patients it took place 4 weeks after admission.
***Long-term patients only.

variables that significantly differentiated the short-term and long-term groups (premorbid adjustment, education, and socioeconomic status). Addition of these covariates tended to further reduce the treatment assignment effect, although it remained at $p<.05$ for the overall severity item of the PEF. Thus, although it appears that there is indeed an effect of treatment assignment favoring long-term hospitalization, this effect also seems to have been spuriously enhanced in our data by chance variation in the random assignment of the patients.

These effects of short and long hospitalization, as measured by the HSRS and PEF global ratings, are shown graphically in figure 1. As previously reported (2), in a similar analysis of covariance short-term patients were found to be more improved on the HSRS just before their discharge than were long-term patients at a comparable time after admission (4 weeks) ($p<.01$). At one year this effect was reversed, however: the long-term group showed significantly greater improvement (see table 1).

We next looked at the tails of the sample to find out which patients were most improved and which were least improved or had gotten worse. At one year, 15 of the 17 patients who improved most on the overall severity item of the PEF were long-term, and 14 of the 26 patients who improved least were short-term ($p<.02$, chi-square test). There was a similar trend on the HSRS, but it did not reach significance.

In summary, at one year there was a global effect favoring the long-term patients.

Posthospital Treatment

In interpreting these results, one must consider the possible intervening effect of the aftercare that many

of these patients received. Since we did not control aftercare experimentally, it was possible for the length of hospital stay to influence the amount of aftercare, which in turn could account for some or all of the differences in functioning seen one year after admission. The long-term patients did, in fact, receive a different pattern of treatment after hospitalization than did the short-term patients, as is shown in table 1. During the final 8 months of the first year after admission, when virtually all of the patients had been discharged from the index hospitalization, long-term patients made significantly more psychotherapy visits. At the one-year follow-up they were receiving medication at significantly higher dose levels (see table 1).

To check whether the number of posthospitalization psychotherapy visits might also be related to sex or baseline summary score of historical data, we computed two further analyses with the number of psychotherapy visits as the dependent variable: a three-way analysis of variance—treatment assignment × sex × admission summary score of historical data (high versus low) and a two-way analysis of covariance (treatment assignment × sex, with the admission summary score of historical data as covariate). Neither sex nor admission summary score of historical data was related to number of posthospital psychotherapy visits, either directly or by interaction with the treatment assignment. In both analyses the treatment assignment (short versus long) main effect was significant ($p<.05$ and $p<.01$, respectively). Similar analyses were computed using the one-year data on chlorpromazine-equivalent medication dosage at the time of follow-up as the dependent variable. Again, the main effect of treatment assignment was significant, but neither sex nor admission summary score of historical data showed main effects or interaction with treatment assignment.

With such complex confounding of the length of hospital treatment with the amount of posthospitalization treatment, it is not possible to be sure how much of the better performance of the long-term patients at one year was due to more aftercare. Nevertheless, we attempted to explore this issue further by including the amount of aftercare as if it were an independent variable (which it is not) in further analyses of global outcomes at one year. The patients were divided into three approximately equal groups according to whether they had a low (0–3), moderate (4–20), or high (21 or more) number of outpatient psychotherapy contacts. We computed analyses of covariance (treatment × sex × amount of psychotherapy) of the three global measures. The linear component of posthospital psychotherapy accounted for a significant ($p<.05$) amount of variance of two of the measures, the HSRS and the summary score of historical data. These are the two most closely related to social functioning, but the third, the PEF overall severity item, focuses more on symptoms. The short versus long treatment effect on the HSRS was entirely eliminated (or "accounted for") by including the aftercare variable. The treatment effect seen in the PEF was not eliminated, but it was somewhat weakened by adding the aftercare variable; it was also complicated by the appearance of two- and three-way interactions of aftercare therapy with short versus long treatment assignment.

Thus, in general, the aftercare variable does seem to relate to one-year outcomes and at least partially accounts for the independent effects of the short or long treatment assignment. In similar analyses of drug dosage at one year, no comparable attenuation of the treatment assignment effect was found. This suggests that the influence of length of stay on subsequent posthospitalization psychotherapy is an important mechanism—perhaps the primary mechanism through which length of stay influences outcomes at one year.

Other Outcome Measures

Analyses were also carried out on the 19 specific symptom ratings of the PEF and a variety of other specific ratings by the follow-up interviewers, by the patients, and by family members. Two of the 19 PEF items, daily routine and belligerence-negativism, showed significant differences ($p<.05$, t test) favoring long-term patients. On the emotional health item of the PSECS, more long-term patients judged their emotional health "much better" or a "a little better" than it was two years before admission, more short-term patients judged it to be the same, and equal numbers of short- and long-term patients judged their emotional health worse ($\chi^2=7.27$, $p<.05$). The remaining measures are summarized in table 1. Although the trends generally favor long-term patients, most do not reach significance.

COMMENT

This study attempts to answer the question of what are the relative benefits of short-term versus long-term inpatient treatment for those schizophrenic patients for whom inpatient treatment is indicated.

To the clinician, the pertinent question is which type of treatment (long-term or short-term) is more likely to result in improvement at one year in a patient who has to be hospitalized. Our data show a modest but statistically reliable difference in global outcome favoring the long-term group. There were no consistent differences between groups on symptoms, work, socialization, or family relationships, but when there were differences, they generally favored long-term treatment.

Our data are consistent with those of Caffey and associates (14), who conducted an experiment similar to ours, in that there was no significantly greater incidence of readmission or better community adjustment (as measured by the KAS) for either group, but our data do show differences (favoring long-term patients) in areas that Caffey and associates did not assess. Our data favoring long-term treatment also need to be considered in the context of two nonexperimental studies comparing community mental

health center inpatient treatment (short-term) versus traditional state hospital treatment (long-term) that favored shorter treatment (4, 15), although our study cannot be directly compared with these studies. Finally, it should be kept in mind that the differences found in favor of long-term hospitalization in the present study, although statistically significant, are of modest size.

The suggestion in our data that the effects of length of hospitalization on outcome are mediated by the amount of psychotherapy the patients received after hospitalization seems important. We speculate that the longer hospitalization allowed for acceptance of the need for therapy on the part of the patient and those important to him or her as well as the need for better arrangements to be made for such treatment. These are advantages sometimes suggested by those who favor long-term over short-term inpatient treatment. Our data do not indicate whether this could be done during a shorter hospitalization or through concerted intervention during the first weeks after hospital discharge. This is a question that must remain for a later study.

In our first paper (1), we began to look at the cost-benefit issue. It is obvious that in this first follow-up year the greater initial cost of the long-term hospital treatment is not offset by a lower cost after hospitalization. Given the differences in outcome, which cannot easily be converted to monetary value, is it worth the greater cost to keep patients in the hospital longer? If society bases the cost-benefit comparison solely on monetary outcomes, then short-term treatment will clearly be the treatment of choice. On the other hand, if society places a high value on the individual patient's adjustment, then long-term treatment might still be considered a viable alternative. A more comprehensive picture of the cost effectiveness of short and long hospitalization will be available when we have the follow-up results for the second year.

Short Versus Long Hospitalization: A Prospective Controlled Study. V. One-Year Follow-Up Results for Nonschizophrenic Patients

BY IRA D. GLICK, M.D., WILLIAM A. HARGREAVES, PH.D., JOAN DRUES, M.A., AND JONATHAN A. SHOWSTACK

The authors studied the effect of long-term versus short-term hospitalization on a group of 74 patients with the diagnoses of affective disorder, neurosis and personality disorder, and hysterical personality one year after their admission to the hospital. Although they had found in an earlier study that short-term patients seemed to integrate more rapidly in the hospital, the results reported in this study showed no statistically reliable differences between the long-term and short-term groups. In contrast to the author's results for schizophrenic patients, their findings for nonschizophrenic patients do not support extended hospitalization.

WE HAVE PREVIOUSLY REPORTED our results for the inpatient phase of this study (1, 2). One-year follow-up results for the schizophrenic patients are reported in the preceding paper. In this fifth communication, we report results of the one-year follow-up of 74 nonschizophrenic patients.

METHOD

Treatment assignment, treatment setting, evaluation, and follow-up procedures for our nonschizophrenic patients were the same as those for our schizophrenic patients. The treatment program for patients with various diagnoses in the study group has been described (2). There were no significant differences between short-term and long-term nonschizophrenic patients in the variables of sex, marital status, race, age, years of education, and socioeconomic status (2). As previously described, the 74 nonschizophrenic patients were grouped for analysis into three diagnostic subgroups—affective disorder, neurosis and personality disorder, and hysterical personality disorder. We were able to locate and enlist the cooperation of 33 short-term and 34 long-term subjects (91% of the original sample of 74 subjects).

The authors are all with the Cinical Research Ward, Langley Porter Institute, University of California, San Francisco, Calif. 94143. Dr. Glick is Associate Professor of Psychiatry in Residence, Dr. Hargreaves is Associate Professor of Medical Psychology in Residence, Ms. Drues is Staff Research Associate, and Mr. Showstack is Staff Research Associate II.

This study was supported by Alcohol, Drug Abuse, and Mental Health Administration grants MH-20593, MH-12450 (Career Teacher Award to Dr. Glick), and MH-36809 (Research Scientist Development Award to Dr. Hargreaves) from the National Institute of Mental Health, and by grant FR-00122 for computing services to the University of California, San Francisco, from the National Institutes of Health.

RESULTS

Global outcome at one year was measured by the HSRS, the PEF overall severity of illness item, and the summary score of historical data, described in the preceding paper. Two analyses of covariance were computed for each of these three measures: treatment assignment × sex and treatment assignment × diagnosis. The admission score on each measure was the covariate. We chose not to compute a single three-way analysis of covariance because cell frequencies were too small when sex and diagnosis were cross-classified.

The PEF overall severity item showed a significant main effect for treatment assignment favoring the long-term group in the first analysis ($p < .05$) and a similar trend ($p < .10$) in the second analysis. Neither sex nor diagnosis produced significant main effects in their separate analyses, nor were there significant interactions of treatment assignment × sex or treatment assignment × diagnosis. Parallel analyses of the HSRS and the summary score of historical data produced no significant main effects or interactions.

In other words, at one year there was no differential response to long-term or short-term treatment for all three nonschizophrenic groups except for a slight but statistically significant effect favoring long-term treatment on the PEF overall severity item. There were no differences either between men and women or among the three diagnostic subgroups (affective disorder, neurosis and personality disorder, and hysterical personality disorder) on any of the three global measures.

We had previously found that the admission summary score of historical data of schizophrenic patients was highly correlated to the one-year outcome scores; this was also true for the nonschizophrenic patients.

We therefore repeated the above analyses, using the admission summary score of historical data as the covariate. The results of these analyses are essentially the same as reported above.

Analyses parallel to those reported in the preceding paper were done for symptoms, family functioning, posthospital treatment, use of leisure time, socialization, and role functioning. There were essentially no differences between short- and long-term patients in these areas of functioning. The study results are summarized in table 1.

COMMENT

The results for nonschizophrenic patients suggest that at one year long-term treatment may be slightly more effective than short-term treatment, but the findings are much more equivocal than they were for the schizophrenic patients. There are no similar studies reported that support greater benefit for either type of treatment for nonschizophrenic patients. On the whole, our results do not provide strong support for the use of the more expensive longer hospitalization

TABLE 1
Summary of Outcome Measures for Nonschizophrenic Patients One Year After Short or Long Hospitalization

Item	Range of Measure*	Short-Term Patients	Long-Term Patients	Test of Significance	Significance
Global measures (adjusted means)					
HSRS	1–100*	48.3	53.1	Analysis of covariance	n.s.
PEF overall severity item	1–6	3.3	2.6	Analysis of covariance	$p < .10$
Summary score of historical data	−1.20–+2.82	−0.26	−0.37	Analysis of covariance	n.s.
Posthospitalization treatment measures					
Number of readmission episodes	—	7.0	13.0	Chi-square test	n.s.
Mean number of days per episode	—	19.3	34.8	Two-tailed t test	n.s.
Number of patients rehospitalized	—	5.0	8.0	—	—
Number of patients not rehospitalized	—	26.0	26.0	—	—
Analysis (patients rehospitalized versus those not)	—	—	—	Chi-square test	n.s.
Mean number of days in hospital	—	4.4	13.3	Two-tailed t test	n.s.
Mean number of psychotherapy visits	—	12.0	17.1	Two-tailed t test	n.s.
Symptom measures					
PEF disorganization scale (adjusted means)	1–6	1.4	1.3	Analysis of covariance	n.s.
PEF subjective distress scale (adjusted means)	1–6	2.5	2.2	Analysis of covariance	n.s.
PEF antisocial scale (adjusted means)	1–6	1.4	1.4	Analysis of covariance	n.s.
PEF withdrawal scale (adjusted means)	1–6	2.2	1.7	Analysis of covariance	n.s.
PEF grandiosity-externalization scale (adjusted means)	1–6	1.6	1.4	Analysis of covariance	n.s.
PSECS emotional health item (means)	1–5	2.3	1.8	Two-tailed t test	n.s.
FMECS emotional health item (means)	1–5	2.1	1.5	Two-tailed t test	n.s.
Family functioning measures (means)					
PEF mate role item***	1–6	2.9	2.9	Two-tailed t test	n.s.
PEF parent role item***	1–6	3.8	1.8	Two-tailed t test	$p < .02$
PSECS family item	1–5	2.5	2.2	Two-tailed t test	n.s.
FMECS family item	1–5	2.2	1.8	Two-tailed t test	n.s.
Leisure time and social activities measures					
KAS for patients socially expected activities scale (adjusted means)	9–48**	33.4	34.0	Analysis of covariance	n.s.
KAS for relatives socially expected activities scale (adjusted means)	9–48**	31.5	32.6	Analysis of covariance	n.s.
KAS for patients free time scale (adjusted means)	10–65**	37.7	39.0	Analysis of covariance	n.s.
KAS for relatives free time scale (adjusted means)	10–65**	40.5	38.8	Analysis of covariance	n.s.
PSECS social life item (means)	1–5	2.3	2.0	Two-tailed t test	n.s.
FMECS social life item (means)	1–5	2.3	1.7	Two-tailed t test	n.s.
Work measures (means)					
HIF role functioning item	1–4**	2.2	2.2	Two-tailed t test	n.s.
Number of months unemployed	0–8	4.1	3.6	Two-tailed t test	n.s.
PEF wage earner item***	1–6	2.5	1.9	Two-tailed t test	n.s.
PEF housekeeper item***	1–6	1.8	1.4	Two-tailed t test	n.s.
PEF student trainee item***	1–6	1.6	1.0	Two-tailed t test	n.s.
PSECS work item	1–5	2.3	2.3	Two-tailed t test	n.s.
FMECS work item	1–5	2.1	1.6	Two-tailed t test	n.s.

* Unless otherwise noted, a low score indicates better adjustment.
** A high score indicates better adjustment.
***There were missing data for a large number of patients on these items. The numbers of patients for whom data were available on the PEF mate role item were 7 short-term patients and 13 long-term patients. The respective numbers for the PEF parent role item were 5 and 10; for the PEF wage earner item, 15 and 16; for the PEF housekeeper item, 18 and 17; and for the PEF student trainee item, 7 and 5.

for nonschizophrenic patients. It is possible, of course, that the sample was too small, the measuring instruments used were insensitive to the relevant outcomes for this group, or greater differences between the two treatment groups will emerge in the two-year follow-up results.

Journal Policy on Multiple Authorship

It has come to our attention that there has been some misunderstanding regarding the *Journal*'s policy on polyauthorship. The number of authors listed on a paper is not a factor in the review and acceptance/rejection procedure. However, once a decision has been made to publish a paper, we do apply *Journal* policy regarding the number of authors in the by-line: only principal researchers and writers of articles are listed in the by-line; collaborators who have provided technical and other assistance are acknowledged in a footnote. In papers that list more than 4 people as principal authors, we query the first author to verify that those individuals were substantial contributors to the research or ideas reported. Since certain types of psychiatric research may require multiple workers, we will of course include all of the names in these cases.

Limitations of Brief Hospital Treatment

BY STEPHEN REIBEL, M.D., AND MARVIN I. HERZ, M.D.

A total of 175 newly admitted inpatients who lived with their families were randomly assigned to three treatment groups: standard inpatient care and brief hospitalization with and without transitional day care. Case reports of 6 of the 9 patients considered "study failures" illustrate that effective postdischarge adaptation is limited by the patients' degree of impairment as well as the family and community capacity to accept them. Although rapid return to the community is beneficial to many patients, rigid adherence to this policy is neither wise nor clinically effective.

IN RECENT YEARS there has been a distinct trend toward brief rather than long-term hospitalization for the mentally ill and an attempt to provide psychiatric care within the patient's community rather than in large, geographically remote state hospitals. The deleterious effects of prolonged custodial care in large government institutions have been described by Goffman (1), Gruenberg (2), and others. Not only state hospitals but also psychiatric units of general hospitals and community mental health centers have attempted to shorten inpatient stays. While it appears that for most patients brief hospitalization is preferable to prolonged hospitalization (3–7), there are some patients who need long-term inpatient care. This paper describes a group of patients who were found to be unsuitable for brief hospital care and who required more lengthy inpatient treatment.

In 1971 a controlled study was begun on the Washington Heights Community Service of the New York State Psychiatric Institute to evaluate the relative efficacy of brief hospitalization (1 week or less) and discharge at the therapist's discretion (standard hospitalization) (3). Because we were interested in the effects on families as well as patients, only patients who lived with families were included in the study. The study design provided that no patient should be discharged from inpatient care if it were clearly detrimental to his own or his family's welfare.

In spite of intensive efforts to adhere to the study design, 9 out of 112 patients were considered "study failures" in that they could not be treated by brief hospitalization. They are to be distinguished from other patients assigned to brief treatment who did relatively poorly and required frequent rehospitalization but for whom there was no compelling reason to discontinue the "brief" paradigm. In the case of the 9 study failures, it was judged that any further attempt to limit the duration of hospitalization would be clearly detrimental to the welfare of the patient or his family. The purpose of this paper is to describe 6 of these 9 patients and their social situations. We feel that they document the limitations of brief hospital treatment and the continued need for lengthier hospital stays for a small but significant proportion of patients.

METHOD

Subjects

The study was conducted on the Washington Heights Community Service, which is responsible for a catchment area with a population of 90,000 in an ethnically diverse low-income area of upper Manhattan.

All patients admitted to the inpatient service were evaluated for possible inclusion in the study on the first weekday following their admission. The attending psychiatrist and the patient's therapist (a psychiatric resident or psychology intern) conducted the evaluation. A total of 175 patients entered the study. It is important to note that all patients accepted in the study had to have a responsible adult willing to provide some supervision at the time of discharge.

Treatment

Immediately after they were evaluated for inclusion in the study, patients who met the criteria were randomly assigned to one of the following treatment groups.

1. *Standard-out group* (N=63). Standard hospital procedure was followed, i.e., the length of hospital-

A brief version of this paper was presented at the 51st annual meeting of the American Orthopsychiatric Association, San Francisco, Calif., April 8–12, 1974.

The authors are with the Washington Heights Community Service, New York State Psychiatric Institute, 722 West 168th St., New York, N.Y. 10032, where Dr. Reibel is Director, Outpatient Service, and Dr. Herz is Director.

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration grant MH-19831 from the National Institute of Mental Health and by the New York State Department of Mental Hygiene.

The authors wish to thank Drs. Jean Endicott and Robert Spitzer for their collaboration in this study.

ization was determined by the patient's therapist and the attending psychiatrist in consultation with the rest of the clinical staff. When inpatient care was no longer deemed necessary, the patient was discharged into the community and followed, if appropriate, as an outpatient.

2. *Brief-day group* (N=61). Every attempt was made to discharge patients from inpatient care to aftercare within 1 week. Patients and their families were told that in all probability the patient would be discharged from inpatient care within 1 week but would receive appropriate aftercare. When the patients were discharged from inpatient care, they could receive day care unless it was considered unnecessary. Patients who received day care came to the hospital each weekday at 8:30 a.m. and left to go home at 4:30 p.m. There was no separate program for day patients. While at the hospital, they participated in the same program with the same staff as the inpatients. Discharge from day care was at the therapist's discretion, with outpatient treatment provided when appropriate. Acceptable reasons for prolonging the inpatient hospitalization included suicide risk, possibility of violent behavior, and extreme disorganization. Whenever a patient was not discharged within 1 week, the reasons were recorded on a form.

3. *Brief-out group* (N=51). Inpatient treatment was identical to that of the brief-day group. Day care was not offered, i.e., brief hospitalization was followed by full discharge into the community with outpatient therapy when appropriate.

Once a patient had been assigned to a treatment group, he was reassigned to the same group on subsequent readmissions during the entire follow-up period of the 2 years after initial admission. All patients were treated on the same 55-bed inpatient ward, which has an open-door policy except for a closed 10-bed intensive care unit. Patients in the 3 groups were treated by the same staff and participated in the same activities during the day. The ward program was group oriented, with a strong emphasis on activation of patients. A full range of psychiatric treatments was used, including individual psychotherapy, group, family, milieu, and somatic therapy, and vocational rehabilitation. The inpatients generally spent 24 hours a day in the hospital. Except for weekend or overnight passes, all inpatients slept at the hospital. Day patients began their treatment by spending the full 8 hours during the day at the hospital from Monday through Friday. Later participation would be reduced if deemed appropriate.

Weekly meetings of the research and clinical staffs were held to review the status of each study patient. The determination that brief hospitalization was proving to be inappropriate or harmful to a patient or his family was made at these meetings. Once this determination was made, no time limit was placed on the patient's hospital stay and he was considered a "brief hospitalization failure." Reasons for this decision were recorded on a special form.

RESULTS

The 9 patients described in this paper who were study failures were compared to the total sample by means of the Social Background Record (SBR) (8) and the Psychiatric Status Schedule (PSS) (9). The SBR revealed that the "failure" subgroup was significantly more likely to be younger, single, and schizophrenic (paranoid or chronic) than the rest of the sample and more likely to have had more previous hospital admissions ($p<.05$, t test). The only differences noted on the initial PSS scores were significantly more overt anger in the "failure" subgroup ($p<.05$) and a tendency toward more impairment in their roles as parents and housekeepers.

By examining these cases carefully we hoped to define patients and situations that do not lend themselves to brief hospital treatment as well as to provide some basis for prescribing appropriate treatment on initial evaluation. A description of 6 patients whose psychopathology and life situations did not permit brief hospital treatment follows.

CASE REPORTS

The first 2 patients to be discussed were assigned to the brief-day group. The failure of this form of treatment is of particular significance since a short period of in-hospital treatment followed by partial hospitalization is being increasingly used as an alternative to long-term hospitalization.

Case 1. A 23-year-old single Ecuadorean man with a diagnosis of schizophrenia was brought to the hospital by his brother because of extreme social isolation, psychological withdrawal, and self-neglect. The brother professed his willingness to have the patient return to live with him following discharge. The patient was rehospitalized 5 times within 1 year; it was during the last hospitalization, which lasted 65 days, that the patient was considered a "brief hospitalization failure."

The staff's effort at short-term hospitalization was based on the assumption that the patient could return to his brother's home. Eventually the staff learned that the brother planned to marry and no longer wished to care for the patient. The treatment plan actually intensified the conflict between the patient and his brother. After the brother admitted that he could no longer care for the patient, a suitable plan involving residential placement was formulated. As a result both the patient's mental status and his relationship with his brother improved.

Case 2. A 21-year-old single, mildly retarded Puerto Rican woman was admitted to the hospital and placed in the brief-day group after a 3-day period of increasing confusion and agitation. She seemed to have a relatively stable home situation. Her behavior in the hospital was wildly bizarre and provocative as efforts were made to introduce her to the day hospital regimen.

In this case, the pressure for rapid return home with day hospitalization was inappropriate. The degree of the patient's psychopathology and disorganization precluded

her understanding and participating in a program that required that she adjust to living both at home and in the hospital. It was evident that her panic and disorganization required a longer period of hospitalization, and she was judged to be a "brief hospitalization failure" 5 months after admission. After several months of hospitalization in a distant state hospital she was able to return home, obtained a job, and began a promising relationship with a young man.

The following patients were randomly assigned to the brief-out group. This treatment placed more stress on the staff for rapid intervention and higher expectations on the patients and their families since day hospitalization was not available.

Case 3. A 17-year-old single girl, a high school senior, was admitted to the hospital following a suicidal gesture involving an overdose of barbiturates. The precipitating event seemed related to the impending dissolution of her parents' 25-year marriage. There had been severe and open discord for years. Attempts to discharge the patient into this deteriorating situation involved her repeatedly in pathological family interactions, and she required 4 readmissions in 5 months. She was transferred to and did well on a long-term inpatient service.

Case 4. A 20-year-old divorced mother of 2 was admitted to the study at the time of her fourth hospitalization in little over a year. At the time of admission she had stopped taking her medication and was hallucinating accusatory voices.

The patient was unable to live either with her abusive alcoholic mother or independently with her children. Her conflicts around this choice led to repeated suicide attempts and eventually necessitated involuntary commitment. When she was encouraged to live by herself in the sheltered setting of a halfway house, her suicidal behavior ceased.

Case 5. A 22-year-old single, unemployed man of massive proportions was admitted to the hospital in a confused and agitated state. This was his first hospitalization. The patient, who was black, had a long history of antisocial behavior and vague and grandiose delusions concerning the Black Muslims.

The patient was discharged within 1 week in accordance with the protocol but within 2 days was arrested for purse snatching. He was sent to prison to await trial. However, due to the hospital's intervention he was placed on probation and transferred to our custody. Because of these legal entanglements he was dropped from the study. Various efforts were made to engage him in rehabilitation through vocational counseling, training programs, etc., but he was unable to follow through on any of these. After 6 months of such efforts, the patient was discharged but was quickly readmitted because of another incident of purse snatching. His management in the hospital was difficult because of continued petty thievery and occasional violence. Efforts to place the patient in a residence for the mentally retarded were unsuccessful, and he was discharged to his family. Three months after his final discharge the patient was arrested for stealing a neighbor's television set and was sent to a correctional institution.

A combination of this patient's antisocial traits, limited intelligence, poor judgment, impulsivity, and episodic psychotic disorganization make life for him in the community a doubtful proposition. Such patients account for many of the sensational news media stories concerning discharged psychiatric patients. There are currently no institutions specifically designed to deal with them. Any effective treatment program would have to include legal sanctions. At the moment these patients are lost between the boundaries of criminal justice and psychiatric care systems. This neglect benefits neither them nor their potential victims.

Case 6. A 37-year-old separated mother of 5 from Santo Domingo was admitted to the hospital for the first time following an overdose of chlordiazepoxide (Librium). Her symptoms of insomnia, anorexia, and anhedonia were clearly related to the breakup of her marriage of 20 years and her continuing struggle with her husband over financial support. As time for discharge approached, the patient made dramatic assertions of suicidal intent that were sufficiently frightening to the staff for her to be placed in the intensive care unit.

This nonpsychotic woman was hospitalized because of provocative and largely manipulative suicidal behavior. She manifested this behavior in order to express her anger toward her husband and to avoid maternal responsibilities that she experienced as overwhelming. Pressure for early discharge led to a power struggle. When the staff adopted a policy of not setting a definite discharge date, the patient ceased her regressive behavior within a few weeks and requested discharge.

DISCUSSION

In a study of brief hospitalization conducted on the Washington Heights Community Service, all but 9 of 112 patients were treated according to the protocol. Standardized test scores showed that the subsample had more overt anger and more previous hospitalizations than the rest of the study sample. However, the differences were not great. Family, social, and individual factors were all relevant to some extent. The comments concerning each case represent our conceptualization of the relevant problems.

Persistent poor judgment and impulsive behavior, with or without mental deficiency, antisocial behavior patterns, and continued psychotic disorganization clearly limit effective postdischarge adaptation as well as the family's and community's capacity to accept and tolerate discharged patients. Patients who are suicidal or assaultive cannot be returned rapidly to the community until these symptoms have abated.

Family-related factors were of great importance in many of the cases. In some, the intensity of family crisis was so severe that rapid return home was clearly detrimental. This was particularly true for adolescents whose families were in severe crisis. In other families, specific patient-family interactions perpetuated and exacerbated the patient's symptoms.

Schizophrenic patients who decompensate after marrying and having children can present special problems. They may gravitate back to their parents and be encouraged to regress into dependent or symbiotic relationships. Brief hospitalization encourages the staff to return patients to their families, but in some instances a more prolonged hospitalization, with the goal of separating the patient from his family, may be more appropriate.

In the past, removing patients from society was felt to be best for the patients, their families, and their communities. More recently, however, mental health ideology has come full circle, advocating rapid return to the community. Our intent is to call attention to the limitations of a rigid adherence to this policy. The fact that all patients in our study had families is of crucial importance. As a result they were in a far better position to benefit from brief treatment than are most patients who are social isolates, such as those described by Reich and Siegel (10). These authors pointed out that the discharge of the chronically dysfunctional, isolated psychotic individual to a foster home he rarely leaves, a "welfare hotel" where he may become the victim of various depredations, or to a wandering skid-row existence hardly represents social concern or the exercise of meaningful personal freedom. At least our patients did have homes to which to return. Nevertheless, brief treatment did not appear effective in these 9 cases.

We believe that rapid return to the community enables most patients to use their assets and discourages regression. Families are unable to use the hospital as a repository for their problems. Nevertheless, a rigid adherence to the policy of brief hospitalization for all is neither wise nor clinically effective. Only a careful assessment of each case can determine the appropriateness of hospital discharge. It is necessary to recognize that hospitalization is only one component of a comprehensive health care delivery system that should include halfway houses, supervised residences, sheltered workshops, and aggressively carried out aftercare. Without the availability of such comprehensive community care, there is a distinct danger that enthusiasm will give way to cynicism and a return to custodial institutions.

Finally, there is a small group of chronically ill patients, characterized by gross psychotic disorganization, markedly impaired reality testing, and extremely poor judgment, for whom the most humane environment may be the state hospital with the protection and support that it affords. Certainly mental health care delivery systems must include some provision for patients who require more prolonged institutionalization.

Psychosis, Thought Disorder, and Regression

BY NANCY C. ANDREASEN, M.D., AND PAULINE S. POWERS, M.D.

Although thought disorder is widely considered to be pathognomonic of schizophrenia, the role of thought disorder and regression in psychosis has not been systematically evaluated with psychometric techniques. The authors used a sorting behavior test to compare five cognitive processes in schizophrenic patients, manic patients, and normal children and adults. They hypothesized that the two psychotic groups would have scores similar to those of the children, which would reflect the tendency of psychotic individuals to display regressive thinking and autism. It was found that the cognitive styles of the children and the manic patients were strikingly different, but that those of the children and the schizophrenic patients were similar.

AT LEAST since the time of Bleuler, the concept of thought disorder has been central to the definition of schizophrenia. Bleuler tried to determine the fundamental disturbances that underlie the illness, rather than examining superficial clinical symptoms, and he thought that the cognitive disturbance was perhaps the most basic (1). In an era of "association psychology," Bleuler emphasized that schizophrenic patients suffered from loosening of associative threads, or an inability to see connections between things:

> Of the thousands of associative threads which guide our thinking, this disease seems to interrupt, quite haphazardly, sometimes such single threads, sometimes a whole group, and sometimes even large segments of them. In this way, thinking becomes illogical and often bizarre. (1, p.14)

Bleuler's influence on the concept of schizophrenia has been significant, and many psychiatrists follow his precedent and consider thought disorder pathognomonic of schizophrenia.

Later theorists, particularly those who use psychoanalytic concepts, have tended to use the idea of regression to earlier stages of adaptation to explain schizophrenic thought disorder. According to these investigators, schizophrenic thinking shows the same symbolism and lack of ordinary logic that one observes in dreams or in the thought and speech of children (2–8). Explanations of this similarity vary, depending on the point of view of the theorist. Some stress the importance of withdrawal in the face of overwhelming anxiety, while others hold that the breakdown of the governing power of the ego and superego may reveal uncensored primary process thinking. Whatever their particular emphasis, many theorists have stressed the regressive and primitive qualities of schizophrenic thinking.

Some recent discussions of thought disorder have suggested that reevaluation of these basic concepts and theories is needed and have seriously questioned the notion that thought disorder is pathognomonic of schizophrenia. Reed (8) argued that schizophrenic thought disorder differs from normal thinking in quantity rather than in quality. In one investigation, a group of clinicians was unable to distinguish speech and writing samples taken from schizophrenic patients, manic patients, and well-known creative writers (9). Other investigations have suggested that thought disorder occurs in manic as well as schizophrenic patients and that they may show even more thought disorder than schizophrenics (10, 11). Now that the biological model is being applied more widely to schizophrenia, the importance of psychological concepts like regression is being questioned by some. Although widely discussed on a theoretical level, the role of regression in producing schizophrenic thought disorder has not been subjected to quantitative scrutiny.

METHOD

This investigation examined, using quantitative psychometric methods, thought disorder and regression in psychotic individuals. We compared cognitive processes in four groups: schizophrenic patients, manic patients, normal children (6 to 10 years old), and normal adults. We assumed that the scores of the children could be used to measure regression and that the adults would act as a control group whose scores would represent a baseline measurement.

Cognitive Processes

The psychometric measure used was the Goldstein-Scheerer Object-Sorting Test (12). In this test, sub-

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

When this work was done, the authors were with the University of Iowa College of Medicine, 500 Newton Rd., Iowa City, Iowa 52242, where Dr. Andreasen is currently Assistant Professor of Psychiatry and Dr. Powers was a resident in psychiatry. Dr. Powers is now Assistant Professor, Department of Psychiatry, University of Southern Florida, Tampa, Fla.

jects are asked to sort a set of 29 objects (e.g., nails, a hammer, a red rubber ball, a red ashtray) into "groups that belong together." The "handing over" method of administering the test was used, with a total of eight starting points, which were all predetermined by the examiner. After each sorting, the subject was asked to explain why he had sorted the objects in that manner and his answer was recorded. The test results were then coded to conceal name and diagnosis and were randomly mixed. Both investigators scored them independently on a blind basis for behavioral overinclusion, conceptual overinclusion, idiosyncratic or autistic thinking, richness, and underinclusiveness, using the criteria described by Harrow and associates (13–15)[1]. Ratings were usually quite close, but after rating independently both investigators discussed their ratings and reached a consensus score for each subject.

The cognitive qualities were measured according to the following criteria:

1. Behavioral overinclusion. Total number of objects sorted in response to eight starting points.

2. Conceptual overinclusion. Scored on a 1 to 5 scale, with 1 representing normal logical sortings and 5 maximum overinclusiveness. Sorting behavior leading to high ratings included using vague or unrelated concepts to arrange groups, arbitrarily changing starting points, or "force fitting" objects into a category in which they did not belong.

3. Autistic thinking. Scored on a 1 to 5 scale, with 1 representing no autistic behavior and 5 extreme autistic behavior. High scores were assigned for using the sorting starting point in reference to personal experiences, using it as a cue understandable only to the subject, or engaging in inappropriate or strange behavior while sorting.

4. Richness. Scored on a 1 to 5 scale, with 1 representing no richness and 5 maximum richness. High scores for richness were assigned when subjects saw dimensions in the starting point that were appropriate but were rarely seen by others. For example, symbolic sortings (recognizing a group of oblong objects as phallic symbols), seeing each starting point in a fresh or different way from other starting points so that many concepts were used in the course of testing, or consistently making clear logical sortings resulted in high scores for richness.

5. Underinclusiveness. Scored on a 1 to 5 scale, with 1 representing no underinclusiveness and 5 maximum underinclusiveness. Behavior leading to high ratings on underinclusiveness included inability to sort in response to a starting point, incomplete sortings, and repeatedly using the same categorizing principles.

Sample

The sample tested consisted of 18 schizophrenic patients, 16 manic patients, 30 normal children, aged 6 to 10, and 21 normal adults. Patients were screened prior to testing by one of the investigators to determine if they met the diagnostic criteria for inclusion in the schizophrenic or manic groups.

All patients included in the manic group were required to meet the following criteria: 1) presence of at least four of eight symptoms of mood disorder (racing thoughts, grandiosity, pressured speech, increased sociability, early awakening, increased sex drive, irritability, financial extravagance) for periods lasting more than 2 weeks; 2) presence of at least five depressive symptoms (e.g., dysphoric mood, decreased appetite, weight loss, decreased sex drive, insomnia, disturbed diurnal rhythm, suicidal thoughts, crying spells, guilt feelings, decreased concentration), including at least two physiological symptoms, for periods lasting more than 3 weeks; 3) full remission between episodes of mood disturbance.

Patients included in the schizophrenia group were required to exhibit: 1) absence of mood disturbance (depression or elation); 2) symptoms lasting more than 2 months; 3) at least one of three cognitive symptoms (Schneiderian first-rank symptoms, delusions, or auditory hallucinations) in the absence of recent drug intake or excessive use of alcohol; 4) at least one of three behavioral symptoms (social withdrawal, poor work history, or poor heterosexual adjustment).

All patients tested had been admitted because of acute onset or exacerbation of symptoms; they did not differ significantly in age, sex, or educational background. Both manic and schizophrenic patients had a mean of 12.5 years of schooling. The mean age of the manic patients was 32; that of the schizophrenic patients was 29. Patients were usually tested within 1 week of admission. Nearly all were receiving medication at the time of testing, usually phenothiazines or lithium or both, but none was close to clinical remission.

Fifteen first-graders (ages 6 to 7) and 15 fourth-graders (ages 9 to 10), who were randomly selected from all the students in these grades (except those evaluated by their teachers as having below-average intelligence) at an elementary school in a small rural farming community, were tested. The adult group consisted of 21 individuals with no history of psychiatric disorder. The adults tested had a mean age of 33 and a mean of 13.8 years of formal schooling.

Analysis of Data

Data were analyzed by analysis of variance. The manic and schizophrenic groups were compared by t tests to the adults, who were considered a control group; t tests were also used to compare the manic and schizophrenic patients to the children, who were considered to be an index of regression. Scores of the first- and fourth-grade children were pooled, although the older children showed more behavioral overinclusion and less underinclusion, because the children as a group varied in the same direction in comparison with the other three groups. It was hypothe-

[1]Reference (15) is available on request from M. Harrow, Department of Psychiatry, University of Chicago, Ill. 60637.

sized that the two psychotic groups would have scores different from those of the normal adults and similar to those of the children, which would reflect their tendency to regress cognitively and to express autism.

RESULTS

As table 1 indicates, the differences among the four groups revealed by an analysis of variance were significant in most of the areas assessed by the Goldstein-Scheerer Test. Only in richness did the four groups fail to show a significant difference. The variance among groups was highly significant in behavioral overinclusion, conceptual overinclusion, and autistic thinking; the groups also differed in underinclusiveness, but less strikingly.

Tables 2, 3, and 4 indicate the sources of variance among the specific groups based on a series of t tests. In table 2 the manic and schizophrenic groups are each compared to normal adults, who were considered to represent a normal baseline on the various aspects of conceptual style measured by the Goldstein-Scheerer Test. As that table indicates, manic patients differed more from normal adults than did schizophrenic patients. These two groups differed in behavioral overinclusion ($p<.01$), conceptual overinclusion ($p<.001$), and autism ($p<.001$). Schizophrenic patients were also more autistic than the normal adults ($p<.05$), but they were less autistic than the manic patients. Unlike the manics, schizophrenic patients showed significant underinclusiveness when compared to the normal adults ($p<.02$).

The manic and schizophrenic groups are compared to the children in table 3. The manics differed from the children even more strikingly than they differed from the normal adults. They showed more behavioral overinclusion, conceptual overinclusion, and autistic thinking ($p<.001$ for all), and less underinclusiveness ($p<.02$). The schizophrenic patients, on the other hand, tended to have scores quite similar to those of the children. They differed significantly in only one area, autistic thinking, showing more autism at the .001 level.

The hypothesis that data from children can be used as a baseline to measure regressive cognitive style is of value only if the psychometric test used discriminates normal children from normal adults. Table 4 summarizes a statistical analysis of the five conceptual variables measured in the two normal groups. The scores obtained by normal adults on these five conceptual variables are treated as a normal baseline and the scores of the children are compared to them. The children differed significantly from the adults ($p<.01$) on two aspects of the test that measure overinclusive thinking; they scored significantly lower than the adults on behavioral overinclusion and significantly higher on underinclusiveness. They shared this increased underinclusiveness with the schizophrenic group (see table 3), but resembled the normal rather than the schizophrenic adults in their lack of autistic thinking, as one might expect from individuals considered normal.

The mean scores obtained by each of the four groups for each of the five cognitive variables examined indicate that the manic patients are quite different from each of the other three groups. Both psychotic groups are more autistic than the two normal groups. However, if this variable is eliminated, the schizophrenic patients' overall cognitive profile is more similar to the childrens' than to the manic patients'. Thus there appears to be a distinct difference in cognitive style, with manics showing more thought disorder and schizophrenics more regression.

DISCUSSION

The nature of thought disorder is a matter of considerable debate among both psychiatrists and psychologists. Assessing thought disorder by using the Goldstein-Scheerer Test taps only a few aspects among the many that have been discussed. It is useful to view this test as investigating two dimensions: a dimension measuring inclusiveness, with extremes of overinclusive and underinclusive thinking; and a dimension assessing originality of thinking, with extremes of autism and richness. The Goldstein-Scheerer Test does not examine other aspects of thought disorder that are often considered significant, such as inability to think logically, interpenetration of themes, or paraphasias and agrammatisms. It does, however, indirectly evaluate abstractness and concreteness of thinking, since the ability to sort abstractly is built into both the inclusiveness and the richness dimensions, although there is no direct measure of either abstractness or concreteness. In spite of the limitations inherent in the version of the Goldstein-Scheerer Test used in this study, one can make some generalizations about the quality and quantity of thought disorder in mania and schizophrenia.

Manic patients showed relatively more thought disorder than schizophrenic patients when compared to normal adults. In particular, they were markedly higher on the two measures of overinclusiveness and somewhat higher on autistic thinking. This does not necessarily mean, however, that manics have more of all types of thought disorder. Since overinclusiveness is more characteristic of mania than of schizophrenia, we should perhaps discard the concept of overinclusive thinking as a means of explaining schizophrenic thought disorder and should instead begin to apply it to mania. More particularly, we should perhaps speak of overinclusive versus underinclusive thought disorder. If we conceptualize thought disorder in this way, schizophrenic and manic patients are both disturbed in this dimension when compared to normal adult control subjects, but the schizophrenics are disturbed in the direction of underinclusiveness and the manics in the direction of overinclusiveness. Thus, rather than considering thought disorder as pathognomonic of schizophrenia, we should recognize that it occurs in both psychotic illnesses, but in different forms.

If one accepts the assumption that one can measure regression by using the conceptual style of children as a standard, then the notion that schizophrenic thinking is regressive receives some validation from this study. The conceptual profiles of the schizophrenics are similar to those of the children, with the exception that schizophrenics tend to be quite autistic in comparison with normal children. The quality that the schizophrenic group shares with the children is a marked underinclusiveness, and conversely, a lack of overinclusiveness, as well as a lack of richness. This seems to suggest that the poverty of thought often noted in

schizophrenic patients may be a return to more primitive levels of cognitive behavior. Whether this regressive pattern of thinking is due to psychological mechanisms (such as retreat in the face of overwhelming anxiety) or to organic ones (such as a biochemical lesion in areas of the brain devoted to complex integrative or associative functions) is an issue that cannot be resolved by an objective psychometric study of this sort.

Although manic and schizophrenic patients differ strikingly on this measure of regression in that manics show little resemblance to children in conceptual style, both psychotic groups have high scores on autism. Thus, autistic thinking and regressive thinking may not necessarily be the same, although it is often assumed that these terms may be used interchangeably. The autistic thinking measured in this study tends to be bizarre, personalized, and idiosyncratic. Both psychotic groups show this disturbance in thinking, while it is minimal or absent in normal children and adults. The regressive thinking displayed by the schizophrenics, on the other hand, tends to be primitive, narrow, restricted, and unimaginative. It may be of value to separate the concepts of regressive thinking and autistic thinking in future studies of thought disorder, seeing the former as characteristic of schizophrenia and the latter of all types of psychotic disturbances.

Comparisons of clinical symptoms in groups of patients are reliable and valid only to the extent that sampling is accurate. The samples used in this study were based on predefined diagnostic criteria. The boundaries of the schizophrenic sample, in particular, were narrowly drawn, to exclude schizoaffective patients and other schizophrenics with only brief episodes of illness. Although the patients were not all chronic, the schizophrenic sample was nevertheless skewed because patients having symptoms for less than 2 months were excluded. Furthermore, paranoid and nonparanoid patients were mixed because the sample was too small to permit subtyping. Future studies of thought disorder should examine subtypes within the various categories of schizophrenia (schizoaffective versus nonaffective, acute versus chronic, paranoid versus nonparanoid) to determine whether they manifest different types of thought disorder.

Behavioral Changes Following Surgery for Obesity

BY MARK J. MILLS, J.D., M.D., AND ALBERT J. STUNKARD, M.D.

The authors interviewed 69 subjects who had had jejuno-ileal bypass surgery for obesity to determine the relationship between weight loss and eating behavior after surgery. All patients had been extremely overweight; at an average of 37 months after surgery, their mean weight was reduced by 39%. There were four significant postoperative changes: voluntary restriction of food intake, "normalization" of eating patterns, resistance to eating during intense emotion, and far less dysphoria during postsurgical weight loss than during previous weight loss efforts. The authors therefore suggest that factors other than impaired intestinal absorption may account for some portion of postsurgical weight loss.

JEJUNO-ILEAL BYPASS surgery for the treatment of massive and intractable obesity was introduced more than a decade ago (1, 2). The rationale for this procedure was that impairing the absorption of nutrients by radically shortening the small bowel would reduce caloric intake sufficiently to control obesity (3–7) and that this control would continue even in the presence of large intake of food. Favorable responses to this operation have resulted in its cautious and increasing acceptance (8–10), but the original rationale has received little examination (11).

The present study, which was undertaken to test hypotheses that questioned this rationale, derived from prior clinical experience with 12 bypass patients. The hypotheses were as follows: 1) jejuno-ileal bypass surgery is followed by voluntary restriction of food intake, 2) surgery is also followed by an apparently involuntary "normalization" in the pattern of food intake, 3) these reductions of food intake predict the degree of weight loss, and 4) postsurgical weight loss is accompanied by less dysphoria than previous weight losses. Briefly, we anticipated that reduced food intake as well as reduced absorption would be responsible for the weight loss of jejuno-ileal bypass patients.

When this work was done, Dr. Mills was a student at the Stanford University School of Medicine, where Dr. Stunkard is Professor of Psychiatry. Dr. Mills is now a resident in psychiatry, Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, Calif. 94305.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-25568 from the National Institute of Mental Health.

The authors wish to thank Basil M. Meyerowitz, M.D., for providing the study population and for his support of this work, and Helena Kraemer, Ph.D., for assistance in data analysis.

METHOD

The study population consisted of all patients available for follow-up who had been operated on for obesity at the Harold D. Chope Community Hospital, San Mateo, Calif., more than 1 year prior to the study (N=69). All patients were operated on by the same surgeon (Basil M. Meyerowitz, M.D.); 46 received an end-to-side jejuno-ileal bypass wherein 36 cm of proximal jejunum and 10 cm of terminal ileum were anastomosed (12). The remaining 23 patients received modifications of this operation involving slightly less radical resection. After surgery, patients were placed on a recommended regimen of a diet low in fat, spices, and green vegetables. They were told not to drink alcoholic beverages and were given oral vitamins A and D, parenteral vitamin B_{12}, and oral potassium. Oral vitamins E and K, calcium, and magnesium were prescribed as needed. Sixty-two patients received diphenoxylate (Lomotil) to decrease the frequency of bowel movements.

Patients were chosen for surgery on the basis of four criteria: greater than twice predicted weight, good general health, age ranging from 16 to 55 years, and a screening interview with a psychiatrist.

At the time of interview, the population contained 56 women and 13 men whose ages ranged from 21 to 54 years (mean=41±9.9). Sixty-eight percent of the subjects (N=47) had become overweight by age 12, and 93% (N=64) were obese in their twenties (2 of the 5 exceptions were patients who received bypasses in their teens). All had been severely obese for years and had dieted many times without sustained weight loss. Fifty-two percent of the subjects were married, 29% divorced or separated, 6% widowed, and 13% single. Forty-eight percent were Protestant and 35% were Catholic. The mean income was $11,000 per year, and the mean educational level was 12.8 years.

A period of 1 year between surgery and interview was selected in order to ensure that the main weight loss had occurred. The mean interval between surgery and interview was 37±19 months. A total of 82 patients had been operated on at this facility at least 1 year before the study began. At the time of interview, 6 of the 82 had died—1 each from halothane hepatitis,

atherosclerotic heart disease, chronic liver failure, an unidentified neurologic disorder, suicide, and unidentified intraoperative causes. Five had moved out of state; we decided to study only those living in California. We obtained interviews with 69 of the 71 available patients.

Each subject was contacted in advance and interviewed at a place of his/her choice. A structured interview lasting about 50 minutes was conducted by one of us (M.J.M.). The interview involved 104 questions in the following categories: changes in eating habits (N=41), demographic information (N=20), patterns of weight change (N=18), complications of surgery (N=18), and weight loss (N=7).

TABLE 1
Weight Changes in 69 Patients Following Bypass Surgery (in kilograms)

Category	Reported Weight Mean	Reported Weight SD	Ideal Weight* Mean	Ideal Weight* SD	Excess Weight** Mean	Excess Weight** SD
Before surgery	150	26	60	7.6	89	22.0
After surgery	91	17	60	7.6	31	16.0
Difference	59	9	—	—	58	6.0

*Computed from height-weight tables compiled by the Metropolitan Life Insurance Company.
**Defined as reported weight minus ideal weight. Values for this category do not exactly correspond to those of the other two categories because excess weight could not be calculated for 1 subject.

RESULTS

The mean weight loss for all subjects was 59±9 kg. The mean preoperative weight was 150±26 kg, falling to 91±17 kg at the time of examination an average of 37 months after surgery (see table 1). This loss of 59 kg constituted 66% of the total preoperative excess weight and 39% of the total preoperative weight. The mean percentage overweight fell from 149% (range, 80%–238%) to 52% (range, −3.5%–156%) after surgery. At the time of interview, 70% of the subjects reported that their weight was stabilized, 23% that it was decreasing, and 6% that it was slowly increasing. Of the 69 subjects, all but 5 reported weight losses of more than 25%; those 5 had weight losses of 6%, 17%, 18%, 22%, and 24%.[1] There was no significant correlation between the time since surgery and weight (or percentage weight) lost, suggesting that weight had largely stabilized during the year after surgery.

These weight losses contrast sharply with the subjects' previous attempts at weight reduction. The mean maximum weight loss in previous attempts was 25.3±15.2 kg (range, 0–150). Furthermore, these losses were maintained for an average of only 11 days (range, 0–90) in contrast to the more than 25 months of weight loss reported by the patients after surgery.

Hypothesis 1: Voluntary Restriction of Food Intake

Sixty-one patients (88%) suffered from severe postoperative diarrhea. Bowel movements increased dramatically from a preoperative mean of 1.8±2.5 per day to 17±12 in the month following surgery. At examination an average of 37 months after surgery, bowel movements had decreased to a mean of 4.7±3.8. Differences between these means were significant ($p<.01$, Student's t test). All 61 subjects with diarrhea reported rectal tenderness; they also reported voluntarily restricting their food intake in an effort to alleviate this symptom. The 8 subjects without severe diarrhea did not report restriction of their food intake.

Hypothesis 2: Normalization of Eating Habits

The normalization of food intake following surgery was a most striking behavioral change. There was significant normalization in both eating patterns and resistance to eating during periods of intense emotion.

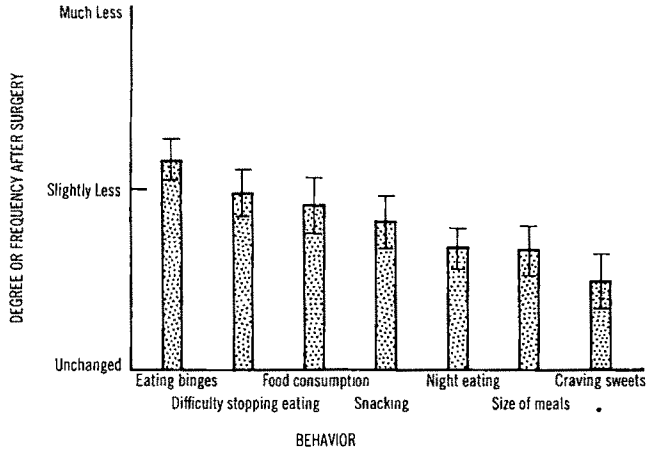
We predicted 10 changes in eating patterns: 1) decreased frequency of eating binges, 2) less night eating, 3) less snacking, 4) less difficulty in stopping eating, 5) reduced craving for sweets, 6) lower alcohol consumption, 7) decreased food consumption in general, 8) less food eaten during meals, 9) fewer meals, and 10) increased frequency of breakfast consumption.

Figure 1 depicts subjects' responses to 7 of the 10 structured questions designed to investigate these predicted changes. There were 5 possible responses; answers were assigned numerical values from 1 to 5, where 1 equals "much more than before surgery" and 5 equals "much less than before surgery." Means, standard deviations, and standard errors were then calculated and Student's t test was applied. Since all of the reported behavioral changes were in the predicted direction (that of normalization), only that part of the scale is presented in figure 1. The 7 predictions related to these questions were confirmed: all values were significantly different ($p<.01$) from no change, the null hypothesis. In addition, the number of meals consumed fell from 3.5±1.7 (range 1–9) before surgery to 2.6±0.8 (range, 1–4) after surgery ($p<.01$). Similarly, 38 persons reported increased frequency of breakfast consumption, while only 11 reported a decrease ($p<.05$, Student's t test). Thus 9 of our 10 predictions were confirmed—the only prediction not borne out by the data was that related to decreased alcohol consumption. Thus, the part of the normalization hypothesis dealing with eating patterns was strongly confirmed.

We also predicted increased resistance to eating during times of intense emotion. Figure 2 depicts the reported changes in eating behavior during periods of intense emotion (6 negative and 2 positive emotions). Re-

[1]Subjects were asked two questions about their weight during the structured interview, one on their weight at the time of surgery and one about their current weight. Therefore it is not possible to report the pattern of weight loss for the group or to determine when the maximum postsurgical weight loss occurred; however, only 4 subjects reported that their weight was increasing at the time of the interview.

FIGURE 1
Changes in Eating Patterns of 69 Jejuno-Ileal Bypass Patients after Surgery



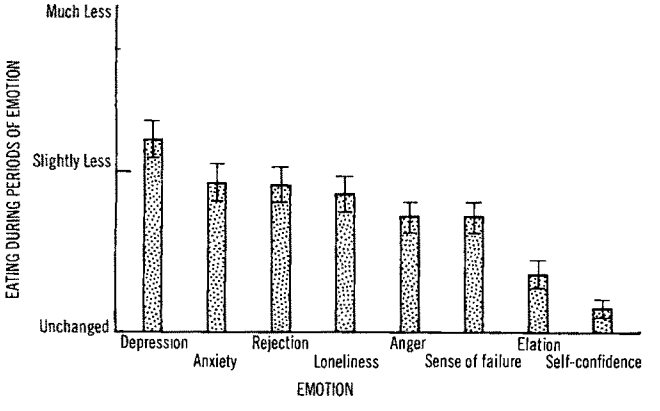


FIGURE 2
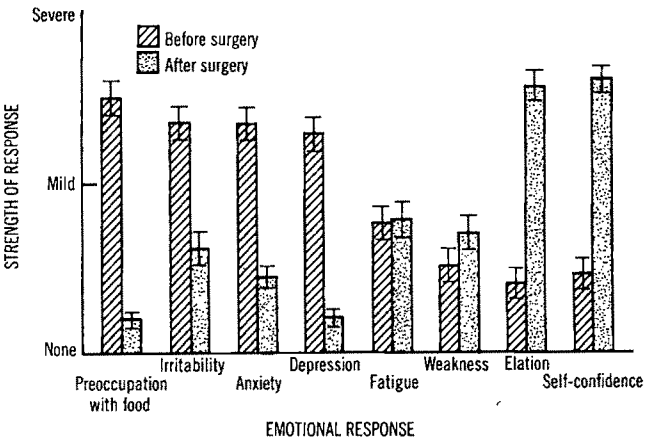
Changes in Bypass Patients' Eating Behavior During Periods of Intense Emotion (N=69)



sponses were ranked in the same way as those related to normalization of eating patterns and similar analyses were carried out. All of the values presented in the figure were significantly different from no change ($p<.01$, except self-confidence [$p<.05$]). The second part of the normalization hypothesis was thus strongly confirmed.

Hypothesis 3: Reduced Food Intake and Reduced Weight

The correlations between percentage of weight lost and both voluntary restriction of food intake and normalization of eating habits were ascertained. The first part of this hypothesis was not confirmed: subjects who reported voluntary restriction of food intake did not differ significantly in weight loss from those who did not.

Since two aspects of the normalization hypothesis were tested, we explored two relationships: 1) the relationship between changes in eating habits and percentage of weight lost and 2) the relationship between

FIGURE 3
Emotional Responses to Weight Loss Before and After Jejuno-Ileal Bypass Surgery (N=69)

increased resistance to eating during periods of intense emotion and percentage of weight lost. The former relationship showed no statistically significant pattern. The latter variables, however, were positively correlated; subjects reporting the largest increase in resistance to eating during intense emotions also reported the largest percentage of weight lost. Table 2 presents the individual changes in eating in response to emotions that were significantly correlated with increased percentage of weight lost ($p<.01$, Spearman rank-order correlation).

Hypothesis 4: Responses to Weight Reduction

Our fourth hypothesis was that subjects would experience less dysphoria during weight loss after surgery than they had experienced during previous attempts at weight reduction. In order to investigate this hypothesis, subjects were given structured questions regarding emotional responses to weight loss, with answers ranked from 1 to 3 (none, mild, and severe). Mean values were calculated for responses related to the preoperative and postoperative periods and differences were analyzed via matched-pairs t tests.

Figure 3 depicts the contrast in emotional responses to weight loss before and after surgery. The four most common untoward responses to weight reduction before surgery (preoccupation with food, irritability, anxiety, and depression) were present to only a slight degree postoperatively ($p<.01$). Two responses to weight reduction, fatigue and weakness, were present to approximately the same degree postoperatively. Two positive emotions, elation and self-confidence, had been experienced by few patients before surgery but were common after surgery ($p<.01$).

PREDICTORS OF WEIGHT LOSS

Three variables in this study were predictors of the percentage of weight lost by each subject at the time of

TABLE 2
Mean Percentage of Weight Lost (± SE), by Susceptibility to Eating During Times of Intense Emotion (N=69)*

	Susceptibility After Surgery					
	More		Unchanged		Less	
Emotion	N	Weight Lost	N	Weight Lost	N	Weight Lost
Depression	1	62±38	21	34±2	47	39±2
Anxiety	1	62±38	29	33±2	39	40±2
Loneliness	1	30±9	35	35±2	33	40±2
Sense of failure	—	—	41	35±1	28	42±2
Rejection	—	—	35	34±2	34	41±2
Anger	—	—	42	34±2	27	42±2
Elation	2	28±11	52	37±1	15	40±3
Self-confidence	1	27±7	62	38±1	6	37±7

* Percentage of weight lost is significantly correlated with emotional susceptibility in each case ($p < .01$, Spearman rank-order correlation).

the interview. There was a significant positive correlation between initial weight and percentage of weight lost ($r=.394$, $p<.01$). The heaviest subjects not only lost the most weight but, surprisingly, actually lost a greater *percentage* of their excess weight. A significant negative correlation was found between age and the percentage of weight lost ($r=-.308$, $p<.01$); younger subjects lost more weight following surgery. There was also a significant positive correlation between decrease in eating in response to anger and weight loss ($r=.359$, $p<.01$). The multiple regression coefficient of the percentage of weight lost versus these three variables was .548 ($p<.01$). More than 30% of the individual variance between subjects in terms of percentage of weight lost was thus accounted for by these three variables.

DISCUSSION

The most striking finding of this study is the degree to which the eating patterns of the subjects tended to change in the direction of those of nonobese people. This change took place both in the general pattern of food intake and in the consumption of food during periods of intense emotion. Some of these changes have been recently reported: less food with each meal (13, 14), less eating between meals (13, 14), eating fewer meals (14), and less night bingeing (13). This kind of change does not occur in the vast majority of patients undergoing weight reduction (15, 16), nor had it occurred in the past experiences of the subjects. This suggests that the circumstances of weight reduction following surgery are quite different from those following traditional methods of weight reduction. The difference applies to such habits as eating binges, night eating, and snacking, as well as to the reduction in eating during intense dysphoric emotions. For the first time in their memory, subjects found that following surgery these emotions did not have the power to elicit eating responses.

The finding that three variables (initial weight, resistance to eating during periods of anger, and age) accounted for more than 30% of the variance in percentage of weight lost suggests, as has been previously proposed (8–10), that subjects for jejuno-ileal bypass surgery should be carefully chosen. Since subjects who were the youngest and the most overweight lost the greatest percentage of their weight, these factors can be added to the criteria for selection of candidates for this surgery.

The final major observation of this study has been previously reported (11) and denied (13) and therefore merits emphasis. This finding is the dramatic decrease in untoward responses and dysphoria during weight loss following surgery as compared with the subjects' previous weight reduction experiences. Weight losses of the degree achieved by our subjects are frequently associated with severe untoward responses, particularly of an emotional nature (17, 18), and this had been true of our subjects. The dramatic decreases in such responses following surgery (illustrated in figure 3), provide support for the use of bypass surgery in the treatment of massive and intractable obesity.

The findings of this study suggest that a major change may occur in the biology of obese individuals following jejuno-ileal bypass surgery. Only some of the changes we have reported were achieved by voluntary efforts on the part of the patients; many occurred without special effort. It was as if the operation had lowered a set point about which the subjects' body weight had been regulated (19). There are at least three factors that may contribute to these profound changes in regulation of body weight. First, surgery may have provided the subjects with "medical evidence" that their obesity was not their fault and in effect gave them a new opportunity to choose more appropriate eating behavior (11, 13). A second explanation is that subjects were aversively conditioned to limit their food intake; the vast majority of the subjects had severe diarrhea and rectal tenderness following surgery, and these symptoms were exacerbated by ingestion of food. Such symptoms provided a powerful

incentive to curtail eating. However, in this study aversive conditioning is not a sufficient explanation of the weight loss of the subjects—those who did not report these symptoms lost as much weight as those who did. A third explanation is that as subjects lost weight they became more active and thus accelerated their weight loss.

In summary, this study has demonstrated that impaired absorption may not account for all the weight loss of patients following jejuno-ileal bypass surgery and that decreased food intake in a variety of circumstances for a variety of reasons may play a part in that loss.

The Significance of Childhood Neurosis for Adult Mental Health: A Follow-Up Study

BY SHERWOOD WALDRON, JR., M.D.

The author compared the mental health of 42 young adults who had suffered from a neurosis in childhood with that of 20 control subjects. Various aspects of functioning were clinically assessed using the Current and Past Psychopathology Scales and the Health-Sickness Rating Scale. More than 75% of the former patients were at least mildly ill at follow-up, compared with only 15% of the control group. Intergroup differences in diagnoses and symptoms are described. The findings establish the fact that neurotic children require much more effective treatment than they have traditionally received in order to attain a good prognosis for adult mental health.

NEUROTIC CHILDREN may be referred for treatment because the presenting symptom itself is distressing, but more commonly treatment is considered on the basis of concern about the child's future development. Because of a lack of adequate follow-up studies, we do not know for certain whether neurotic children have an unfavorable long-term prognosis. Even the demonstration of short-term improvement with treatment (1) does not tell us whether such improvement predicts ultimate adult mental health, and there is reason to think that it does not (2).

The few long-term follow-up studies available (3, 4) suffer from deficiencies in design because they lack either a clinical evaluation of the patients or a control group. It is too hazardous to compare their findings with those of epidemiological studies of psychiatric disturbance in the general population (e.g., 5, 6) because the latter generally use a questionnaire-interview approach by nonprofessionals that may result in misleading conclusions when compared to the results of assessment by clinicians (7).

Several long-term follow-up studies of children suffering from various specific neurotic symptoms (8–13) have suggested the importance of these difficulties to adult mental health. I thought that a long-term follow-up study of neurotic children in general would be more interesting if we studied one of these subgroups as well. I chose children with school phobia because of the evidence that impairment continued into adolescence (13), while the symptom itself tends to remit during childhood with most short-term therapies. Therefore extensive psychotherapy for this condition would ordinarily be indicated only if the long-term prognosis were unfavorable.

For two reasons, I selected the control group from children who were in the same elementary school class as each of our former patients. This sample would presumably reflect the normal expectable outcome for an unselected population, with the omission only of those children too disturbed or damaged to maintain attendance at an ordinary school. In addition, the selection method would serve as an effective control for age, sex, and social class.

We wanted to use a clinical appraisal of these young adults because of the tenuous relationship between indirect measures of mental health and clinical findings. Clinical assessment itself has often been found unreliable (14–16). Fortunately, two instruments have been developed, based upon clinical appraisal, which have shown excellent reliability: the Menninger Clinic's Health-Sickness Rating (HSR) Scale (17, 18), in which ratings are anchored to case descriptions, and the Current and Past Psychopathology Scales (CAPPS), a semi-structured clinical interview with rating scales developed by Endicott and Spitzer at Columbia University (19). These two instruments made possible a follow-up that would be both clinically meaningful and reliable.

Our research group independently assessed the clinical status of the children and their families when they were seen in our clinic in order to provide baseline values that could be compared with outcomes and to clarify the syndrome or syndromes of school phobia. This systematic study has already been reported (20).

Dr. Waldron is Clinical Assistant Professor, Department of Psychiatry, Albert Einstein College of Medicine, Bronx, N.Y. His address is 35 East 85th St., New York, N.Y. 10028

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration grant MH-17945 from the National Institute of Mental Health.

The author would like to thank Diane Shrier, Frances Tobin, and Betty Stone, who evaluated the outpatient charts, and Morton Neril, who interviewed several subjects. Joseph Fleiss supervised the statistical work by the staff of the Evaluation Unit, Division of Biometrics Research, Columbia University. Arnold Rogow, Sander Abend, Charles Brenner, and Lawrence Downs read and critiqued the manuscript. Joseph Cramer's support and suggestions were valuable at several stages of the project.

METHOD

Subjects

A child psychiatrist screened the charts of all patients under age 13 who were first evaluated at our clinic between 1955 and 1962 (N=627). Using the classification of psychopathological disorders in childhood of the Group for the Advancement of Psychiatry (21), we could differentiate between those children who suffered from neurotic disorders or other milder conditions (e.g., reactive disorders or developmental disturbances) and the sicker children. Those who had experienced a school phobia were identified from among the neurotic group. Criteria of classification were first refined in a pilot series of charts, resulting in excellent interrater reliability.

Two-thirds of the over 600 children were considered sicker than neurotic and were excluded from further study. Forty-five of the 203 neurotic children were identified as having had school phobia. We drew up a panel of 35 subjects from the group with school phobia; this was the maximum number that we could study. We then matched one other neurotic child to each of these children with school phobia on the basis of sex, age, age at referral, and year of referral to the clinic. We selected our control subjects from the class that each child with school phobia was attending when the phobia first appeared; from each class we selected the child whose surname alphabetically followed that of the phobic child.

Procedures for locating the subjects were similar to those described by others (4, 22). Considerable persistence and ingenuity were required. Introductory letters were followed by a home visit unless the subject refused. Thus we visited the homes of nonresponders. The home visits were made as far as 200 miles from New York.

Primary Follow-Up Instruments

The semistructured clinical interview (the CAPPS) is of sufficient flexibility to permit the interviewer to explore areas of particular clinical significance as they emerge during the interview. The assessment includes various scales of symptomatology as well as measurements of sexual and interpersonal relationships and functioning in the roles of spouse, parent, housewife, student, and employee. We also added a few other individual scales of particular interest to us. Summary scales have been previously derived by factor analyses of the more than 170 CAPPS scales. A computer program has also been developed which produces reliable and valid psychiatric diagnoses when applied to these scale scores of each individual (23).

Most of the CAPPS scales use a 6-point rating ranging from "none" through "minimal," "mild," "moderate," and "severe" to "extreme" on each dimension rated. We were particularly interested in the overall rating of severity of illness. There is a 6-point severity of illness scale of the CAPPS, which we coordinated with the 100-point HSR scale by achieving a consensus among 3 clinicians as to what points on the 100-point scale corresponded to the 6 degrees of severity of illness specified above. Each time we rated an individual for severity of illness on the CAPPS, we used the case descriptions provided with the HSR scale, gave a rating on the 100-point HSR scale, then converted it to the corresponding score for severity of illness expressed on the 6-point scale (see footnote to table 1 for score conversions). We developed 4 subscales of this overall health-sickness rating, reflecting different aspects of mental health and based upon the 7 subscales originally developed at the Menninger Clinic.

Follow-Up Interviews

I conducted most of the interviews; the rest were done by another child psychiatrist. All of the interviews were tape recorded. Each of us was first trained and evaluated for reliability. Subsequently, ongoing reliability was monitored by independent ratings of an unselected sample of the tape recordings of interviews. Reliability was excellent for the various scales; for example, the most important judgment, the HSR score, showed an intraclass correlation coefficient of .87 between the two raters. Neither interviewer had any knowledge of the old records or of the classification of the subject at the time of the interview, except as the subject revealed it himself in the course of the interview.

RESULTS

We were able to locate 91% of our 105 subjects, of whom two-thirds agreed to be interviewed. We saw 24 phobic subjects, 18 subjects with other neuroses, and 20 controls. Fifty-eight percent of the follow-up group were men. Most subjects were of middle- to lower-class origin. The subjects averaged 22 years old at follow-up; fewer than 5% were younger than 18.

The interviews lasted an average of 3½ hours. The interviews were so lengthy because we encouraged the subjects to discuss their life story in their own way. The interviewer then pursued pertinent lines of inquiry as in a regular initial psychiatric interview. Visiting homes in the absence of a response was important to our success, since one-third of those interviewed had not answered our letters.[1]

We could compare the subjects who were interviewed with those who were not because we had extensive ratings of clinical aspects of the parents and families of virtually all of the former patients in childhood and of the former patients themselves as children. There were negligible differences between the 2 groups of subjects on all ratings from childhood. (See reference 20 for descriptions of the dimensions rated.) This finding reassures us that the 40% of our 105 subjects

[1]Comparison of responders and nonresponders showed negligible mean differences in HSR scores.

who were not seen in the follow-up were probably not very different from those who were seen.

Former Patients

When we compared those persons who had had a school phobia with those who had had other neuroses, we found that the phobic subjects 1) seemed more dependent (29% versus 6%), 2) had a greater tendency to somatize (42% versus 11%), and 3) had had more difficulty completing their secondary school education (25% versus 6%). Aside from these 3 findings, the groups were not distinguishable on our multiple measures. These measures included a number of factors postulated in the literature as typical of school phobics in later years, such as leading lives more centered around the home of origin, tending to avoid new situations, and being more inhibited in the expression of aggression (13). Both groups of former patients were more inclined toward these behaviors than the control subjects were. Because there were so few differences between the 2 groups of former patients, it seemed reasonable to contrast the former patients as a whole with the control group for the remainder of our analysis.

Diagnoses and Health-Sickness Ratings

The school-phobic patients did not differ as a whole from the other neurotic patients in distribution of diagnosis or degree of illness at follow-up. However, there were striking differences in these areas between the former patients as a whole and the control group (see table 1). We found that 40% of the former patients, but none of the controls, received specific diagnoses from the computer program ($p<.01$, chi-square analysis). Twenty-one percent of the former patients were diagnosed as having a specific neurosis,[2] 14% as having a personality disorder including drug dependence, and 5% as being psychotic, although neither of these 2 patients had ever been hospitalized. Thus we found a wide range of psychopathology in the former patients.

The HSR scales showed an even more striking difference between the former patients and the controls: more than 75% of the former patients were at least mildly ill, compared to only 15% of the controls ($p=.001$).

Since diagnoses were derived from computer analysis of the scores on specific variables, whereas the level of illness was a global rating by the interviewer, it is interesting to examine the relationship between the two. There were no specific diagnoses for those who were not ill or minimally ill, whereas close to half of those who were mildly to moderately ill received a specific diagnosis. The author, who is psychoanalytically trained, reviewed the cases of patients who were found to be ill but not diagnosed. All of them appeared to fit into the category of character disorders in the psychoanalytic sense (24), although they were not suitable for a diagnosis from DSM-II (25).

The relationship between the nature and degree of illness of the 2 groups can be summarized as follows: 64% of the former patients were mildly to moderately ill, predominantly with a neurosis or character disorder, while another 12% were severely ill, predominantly with a personality disorder or psychosis. In contrast, only 15% of the control subjects were mildly to moderately ill, all with character disorders. None of the controls was more severely ill.

We were also interested in which of the different aspects of mental health was impaired. The data in table 2 demonstrate that the former patients were quite impaired in the severity of their symptoms and in their interpersonal relationships and less impaired occupationally and in breadth of their interests. In all aspects they were substantially less healthy than the control subjects.

Individual CAPPS Variables

The clinical significance of the subscale differences between the two groups (table 2) can be understood by examining specific clinical differences between them (table 3).

The former patients showed greater difficulty than the controls in functioning as wage earners and as students, with about one-third being impaired. However, the differences between the 2 groups were not so great as in some other areas.

Disturbances in interpersonal relationships were extensive. More than one-fourth of the former patients were more than minimally socially isolated, compared to none of the controls; almost two-thirds had substantial problems in adult sexual adjustment, compared to only one-fifth of the controls. Because many of the subjects were just entering adulthood and therefore would not usually have married yet, we added an assessment of functioning as boyfriend or girlfriend to that of spouse if the relationship seemed enduring and serious. If we examine spouses and boyfriends and girlfriends together, we find that only 50% of the former patients had such a relationship, compared to 80% of the controls ($p=.025$). Of the former patients who did have such a relationship, 52% of them were at least mildly impaired, compared to only 6% of the controls.

There were various symptomatic differences between the 2 groups. Nearly half of the former patients suffered from at least mild depression, compared with only 1 of the control subjects. They also suffered more from anxiety and phobias than the controls, but the differences were not statistically significant. Almost one-fourth of the former patients showed more than a minimal degree of narcotics abuse and/or antisocial behavior and/or belligerence, compared with none of the controls. There were other symptomatic manifestations that were present in small numbers of the former patients; 2 patients had a history of homosexual acts and 1 patient had a perversion. More of the former patients also showed impaired use of leisure time and incapacity for pleasurable activities. In all, there were

[2]Four suffered from depressive neurosis; 2 from hysterical neurosis, conversion type; 1 from phobic neurosis; 1 from anxiety neurosis; and 1 from obsessive-compulsive neurosis.

TABLE 1
Health Sickness Ratings and Diagnosis at Follow-Up of 42 Former Patients (FP) and 20 Control Subjects (C)

many ways in which the former patients appeared to be more impaired than the control group.[3]

Relationships Between the Various Measures

The differences between the former patients and the control subjects on individual variables were reflected in significant differences between the 2 groups on the relevant summary scales. This set of findings bears out the significant differences found in subscales of the HSR (table 2) and adds a partly independent confirmation to the validity of our principal findings. This is because the summary scale scores are founded upon the individual variables, which are usually much more concrete and specific than the HSR subscales, leaving less latitude for rater bias. Intercorrelations between the HSR subscales and summary scales demonstrated the same relatively high degree of relationship between different aspects of mental health as had been previously demonstrated in the extensive study at the Menninger Foundation (26). We know from that study's sophisticated methodology that this is not simply a halo effect but that it reflects a true interdependence between various aspects of mental health.[4]

Unreliability of Symptomatic Assessment

The relationship between symptomatic and clinical aspects of mental health alluded to in the previous section may be examined by classifying a subject as symptomatically ill if he obtained a score representing more than minimal impairment on at least 1 of the symptom variables in table 3. Then one can correlate this measure of illness with clinical illness as defined by a score representing more than minimal illness on the HSR scale. The degree of correlation between the two measures was relatively small for the 2 groups (κ=.46 for the former patients and .49 for the control subjects) (27).

However, separate examination of the degree of illness determined for the former patients and controls reveals an apparent bias in the results of the symptomatic assessment. Among the former patients, almost the same proportion was found to be symptomatically and clinically ill (69% versus 76%). However, a much higher proportion of the controls was found to be symptomatically than clinically ill (35% versus 15%). This difference between the 2 groups was just short of significance despite the small sample sizes (p=.052). Thus we add further evidence to the findings of Dohrenwend and associates (7) and Masterson (28) that symptomatic assessment of controls leads to overdiagnosis of mental illness[5] and that one must be very cautious in making conclusions based upon questionnaire-interview assessments of mental health.

[3]We might not have discovered the actual differences between the former patients and controls if we had assessed them during adolescence instead of young adulthood. Our retrospective assessment of functioning in adolescence showed only small differences in the quality of adolescent friendships, sexual adjustment, and academic performance. A substantial number of the control subjects, as well as the former patients, showed malfunction.

[4]A table of intercorrelations is available from the author upon request.

[5]Robins and Braroe (29) reported a similar finding, although they interpreted it differently.

TABLE 3
Percent of Former Patients and Control Subjects with More Than Minimal Impairment on Various CAPPS Ratings

** One-tailed chi-square analysis was used since the overall trend had been established.

DISCUSSION

Our principal finding is that most of the neurotic children had impaired mental health in adulthood, whereas most of the ordinary school children were not impaired. Is the different proportion of illness found in these 2 groups comparable to findings of previous studies and therefore of general significance? The only controlled study, that of Robins (4), suffers from a lack of direct clinical assessment. Even so, in that study there were significantly more healthy controls than former patients (4, p. 137).

I examined in detail the reported findings of the various clinical follow-up studies (7–13) and found that case descriptions and descriptions of the frequency of various degrees of impairment permit some assessment of whether the degree of illness of those groups is generally comparable with ours. For instance, Levy (10) provided detailed case descriptions of the clinical follow-up picture of 19 children whose mothers were overprotective. Only 2 or 3 of these 19 former patients would appear to be well enough to have been rated healthy or only minimally ill on the HSR. In all, I feel that the findings of all of these studies are quite compatible with ours and demonstrate substantial impairment when account is taken of differing methodology.

It is more difficult to find clinical studies of subjects who are comparable to our control group. We cannot compare our findings with those of the large-scale epidemiological studies for the reasons discussed earlier. I know of only one clinical study of a normal sample in which the levels of illness can be compared with those of our subjects. In that study (7) the low rates of illness for heads of households are quite comparable to those found in our control group. Therefore, such studies as we are able to find support our most important conclusion: children who come to a psychiatric clinic because of neurotic difficulties or developmental disturbances have an unfavorable prognosis for mental health in adulthood. This group of children is not identical to the large proportion of children who develop transient symptoms in the course of development, particularly during the oedipal period (2, 30, 31). For most of these children psychiatric help is not sought.

We cannot determine directly the cause-and-effect relationship between referral for neurotic symptoms in childhood and adult mental health. But it is reasonable to assume that those children who cannot find a more adaptive way to resolve conflicts than the formation of such troublesome symptoms may be demonstrating an impaired capacity for neutralization or an impairment in ego strength that will lead to continuing unhealthy development (32, p. 235).

We cannot say on the basis of our sample whether the unfavorable prognosis applies to all groups of neurotic children. However, we may anticipate the findings to be reported in a later paper by saying that generally, it was not possible on the basis of the clinical pic-

ture in childhood to differentiate those neurotic children who would have good outcomes from the others. It may eventually be established that certain types of neurotic difficulties do not usually result in adult impairment, but there is no evidence from this study to support such a comforting conclusion.

The relationship between outcome and treatment received will also be the subject of a later report. It will suffice here to say that no patient received adequate treatment by psychoanalytic standards. If the treatment received resulted in some improvement for some of these children, then without intervention the former patients would have been, if anything, sicker. Thus our findings make necessary the conclusion that these children need effective treatment. What remains to be established is the validity of psychoanalytic clinicians' impressions that sufficiently careful and intensive treatment in childhood frequently leads to good outcome in adulthood.

One methodological point deserves emphasis: the diagnostic approach to mental health is of somewhat limited utility and there is good reason to emphasize a quantitative assessment of degree of illness, which can be described as a dimensional approach to psychiatric disorder (33). Many areas of medicine have required just such grading of cases as the Health-Sickness Rating Scale provides (for instance, in the outcome of different grades of cervical cancers) before significant clarifications about prognosis can be made. Thus, although the clinical grading of psychiatric cases may not permit us to predict whether a child will develop a character disorder, a specific neurosis, or personality disorder, it does permit us to predict with some accuracy the later degree of illness.

CONCLUSIONS

This study has provided evidence in support of the following points.

1. Children with neurotic difficulties sufficient to bring them to professional attention have a much worse prognosis for adult mental health than normal control subjects. Therefore if any extensive psychotherapeutic technique such as child analysis can be shown to alter this prognosis, it should be used.

2. Depending on the population involved, estimation of the degree of psychiatric disturbance through questionnaire-type interviews administered by nonprofessionals can lead to overestimation of the degree of illness and to substantially incorrect conclusions. Clinical assessment appears to be the only currently available method to avoid this pitfall.

3. Approaching psychiatric illness from the point of view of degree of disturbance offers promising opportunities to enlarge our understanding and predictive powers, which may be obscured by too exclusive an adherence to a nosological approach.

Prompt Publication Policy

The *Journal* would like to remind authors who are particularly interested in early publication (whether to establish priority of an idea, reveal innovative results of new research, or for other pressing reasons) of its prompt publication policy. Under this policy, short (maximum of six double-spaced pages) manuscripts will be considered for publication in the Brief Communications section of the first available issue. These manuscripts must still undergo expert scrutiny before being accepted, and two months must be allowed for the printing process. However, the time required for publication of these short articles can be lessened considerably.

Authors who would like to have their manuscripts considered under this policy should indicate this desire, as well as the reasons for it, when they submit their manuscripts.

Evolution of Behavior Disorders Into Adolescence

BY ALEXANDER THOMAS, M.D., AND STELLA CHESS, M.D.

The New York longitudinal study has followed the development of 136 subjects from infancy into adolescence. The authors report the distribution of diagnoses and outcome of 43 children who developed behavior problems before the adolescent period and the characteristics of 5 new cases diagnosed in adolescence and discuss issues of prediction. The analysis of the longitudinal data for subjects with and without behavior disorders permits discussion of two of the general issues in the literature: the significance of adolescent turmoil and the distinctness of adolescence as a developmental stage.

ADOLESCENCE, with its complex, rapid, and dramatic developmental processes, is a period of special interest to all students of human behavior. It is during this period that the individual comes to physical maturity, establishes his or her emotional independence, begins to achieve an adult level of cognitive functioning, and crystallizes a separate individual psychological and legal identity (1).

For the psychiatrist, the problems of adolescence are indeed challenging. Many of the serious mental illnesses of adult life begin to be evident during this period, but their symptomatic manifestations may be very different than they are in the older individual. The adolescent patient is no longer a child but not yet an adult, and this makes his treatment especially demanding.

Theories of the developmental dynamics of adolescence generally tend to emphasize the conflict of the strivings for individuation, independence, and the establishment of a mature self-identity in the context of the persistent dependent ties to parents and family. Many writers view the tension, rebelliousness, and impulsivity of adolescents as resulting from this conflict and consider such turmoil a normal and necessary consequence of the adolescent struggle for separation, independence, and the beginning of mastery of the adult world (2–6). Others question this concept and caution that adolescent turmoil may in fact signal the development of significant psychiatric disorders (7, 8). Psychoanalytic theory interprets much of the behavior of the adolescent as a "reawakening of oedipal attachments," a period in which "the work of the oedipal period has to be carried out once again" (9).

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

THE NEW YORK LONGITUDINAL STUDY

The New York longitudinal study has provided a special opportunity to investigate several issues in the development from childhood into adolescence. This study has followed the behavioral development of 136 children from early infancy into adolescence. The group is primarily a middle and upper-middle class population with native-born parents. (Demographic characteristics of the sample have been detailed previously [10].)

Forty-three of the 136 youngsters have developed behavior disorders of varying types and severity at different age periods in childhood. The data on the total sample include information gathered longitudinally and anterospectively at sequential age levels from early infancy on related to the child's individual characteristics of functioning at home, in school, and in standard test situations; parental attitudes and child-care procedures; special environmental events and the child's reactions to such events; and intellectual functioning. In addition, psychiatric evaluation has been done for each child presenting symptoms and, wherever necessary, has included neurological examination or special testing. Clinical follow-up of children with problems has also been carried out systematically.

The anterospective longitudinal behavioral and psychometric data, the clinical psychiatric evaluation and follow-up, and the availability of those subjects in the sample without problems as a comparison group have provided a special opportunity to investigate the genesis and evolution of behavior disorders and of specific symptomatology and to test the validity of various theoretical formulations advanced to explain these phenomena. We have also explored the usefulness of counseling procedures for parents that emphasize the development of consonance between the child's temperamental characteristics and the environmental demands and expectations he or she faces. The findings of these studies through the early school years have been reported previously (10–14).

We have conducted separate extended open-ended interviews with each child and his or her parents when he or she reaches the age of 16. The interview covers such subjects as the adolescent's school functioning,

extracurricular activities, sexual involvement, drug use, current problems, future plans, and attitudes toward parents, siblings, and peers. Out of our total sample of 136, 95 have thus far reached age 16; only 5 have refused to be interviewed. All the parents have responded. The 90 adolescents who have been interviewed were generally open and frank in their discussions.

CLINICAL SAMPLE

Of these 95 adolescent subjects, 43 had been diagnosed as clinical cases at an earlier age. Forty of them were described in an earlier work (10); 3 additional cases were identified in the childhood period following that report. Each case was followed up at periodic intervals; the frequency of follow-ups was determined by clinical considerations. With children in direct treatment, the therapist was consulted as to diagnosis and course. On the basis of these data and the new interviews at age 16, the clinical course and outcome was defined for each youngster.

After clinical psychiatric evaluation by one of us (S.C.), 5 additional clinical cases were identified as having started during the adolescent period. These youngsters were referred for this evaluation either by direct parental request or as the result of discussion with our staff interviewer. Other subjects clinically evaluated for similar reasons were judged as behaviorally normal. The criteria for the various diagnostic categories were detailed in our previous report (10).

A number of our findings regarding the adolescent period are currently in preparation (15, 16). This presentation, our second for the adolescent period, will concentrate on the course of the clinical group, the dynamics of the evolution of symptomatology, and predictive issues related to outcome. (Our first report was on the course of 3 youngsters with brain damage [17]).

Table 1 shows the age at onset of symptoms in the 48 cases and the original diagnosis assigned to each case. The largest number of cases came to light during the ages 3–5; the second largest number occurred in children aged 6–8. These cases are, for the most part, a mild reactive type of behavior problem. Very few additional children developed problems during the ages of 9–14. A larger number of new cases then appeared in children 15–18 years old, and these were considerably more serious: 2 neurotic character disorders, 2 neurotic behavior disorders, and 1 moderate reactive behavior disorder.

The findings in this sample conform to general clinical experience. A number of children developed behavior problems, mostly of a mild nature, in the preschool and early school years, very few new cases appeared in the later childhood and early teen years, and then a new group of clinical problems of greater severity developed in adolescence. The disorders in the younger age periods were presumably reactive to the demands for socialization and school adaptation and those in older children to the stresses and conflicts of the adolescent period.

Although the total number of clinical cases seems high, this is a cumulative figure; at any one age period, the number would be much lower due to the number of recovered cases. Also, some of those in the mild reactive category might have recovered spontaneously and not come to psychiatric attention if they had not been subjects in the longitudinal study.

OUTCOME IN ADOLESCENCE

Table 2 shows the outcome in the adolescent period for 42 of the 43 clinical cases diagnosed in the childhood period. (The 43rd case, originally diagnosed as mild reactive behavior disorder at 7.3 years, has not yet been followed up.) As can be seen in the table, 19 cases (almost 50%) recovered, 5 improved, 3 were unchanged, 8 became mildly or moderately worse, and 7 became markedly worse. There was no significant correlation between the severity of the original disorder and outcome in adolescence. It is of interest that very few cases were unchanged—if there was no recovery or improvement, the problem almost always became worse. In all of the cases originally diagnosed as reactive behavior disorder, this worsening led to a diagnostic change to neurotic behavior disorder or neurotic character disorder.

Those youngsters who recovered during the childhood years have remained well in adolescence and appear to be functioning on the same level as the adolescents who did not show behavior disorders in childhood. Recovery cannot be considered spontaneous, since in all cases we extended guidance to the parents. Nineteen cases had direct treatment; 4 of these improved or recovered and several others are still in treatment, the ultimate effect of which cannot yet be evaluated. Of course, some of the children, especially the milder cases, might have recovered spontaneously without any therapeutic intervention.

In a number of the milder cases with rapid recovery, the improvement could be ascribed to the effectiveness of the guidance given to parents, which was directed toward correcting excessive stress on the child created by demands and expectations that were dissonant with his temperamental characteristics. Similarly, lack of improvement or worsening in other cases may have resulted from parents' unresponsiveness to such guidance and advice (10, 14). In some of these cases, the unhealthy parent-child relationship became more stressful and conflict-ridden as the youngster grew older, with corresponding worsening of the behavioral disorder.

In other instances, the reasons for favorable or unfavorable outcome are not obvious, In several cases the overall parent-child relationships were positive, the parents carried through the necessary changes to lessen the excessive demands on the child, and no other sources of unusual stress were evident, yet there was

no improvement in the child's disturbance. In others, a pathological family environment continued, but the child improved or even recovered.

In cases where a pathogenic parent-child relationship persisted into adolescence, we have thus far identified one significant difference between the youngsters who improved or recovered and those who became worse. This involved the adolescent's ability to shift the center of his activities, interests, and emotional commitments from the home and the parents to extrafamilial individuals and groups. Adolescents who achieved this outside identity improved; those who did not grew worse. However, we do not as yet know why one youngster achieved this shift of identity and another did not, or whether the development of a separate identity was the cause or effect of the improvement. Our further analysis of the data is exploring possible correlations with the youngster's temperamental characteristics and special talents or attributes, as well as specific kinds of family pathology.

NEW CASES IN ADOLESCENCE

As noted previously, we have identified 5 new cases with adolescent onset. As a group, these disorders are more severe than those which started in childhood, although there are no instances of psychosis. The symptoms are varied, including depression, hostility, rebelliousness, and antisocial behavior. All of these youngsters exhibit poor performance in school, both academically and behaviorally, and poor impulse control. One girl has a history of neurotic promiscuous heterosexual behavior followed by a homosexual affair. There is no history of sexual problems in the other 4 cases, nor in the clinical cases that started in childhood. Our observation of the total study sample, nonclinical as well as clinical, indicates a wide range of sexual attitudes and behavior (16).

These 5 cases do not permit quantitative comparisons to temperamental characteristics with the rest of the study sample, as was possible with the larger

group of clinical cases starting in childhood (10). In the qualitative analysis of the longitudinal data it has been possible, as with the earlier cases, to trace the evolution of the behavior disorder in terms of an excessively stressful maladaptive interaction between the youngster's temperamental and other characteristics and his family and other environmental influences. However, our review of the anterospective longitudinal data of the childhood period has not as yet revealed any specific characteristics of these 5 adolescents or their families that could have been predictive of the development of pathology. However, our analyses of these data are still in progress and our conclusions are therefore incomplete.

COMMENT

The analysis of the longitudinal data on our subjects, both with and without behavior disorders, enables us to comment on two general issues—the significance of adolescent turmoil and the distinctness of adolescence as a developmental stage.

Many of the youngsters in our study showed one or more of the manifestations usually associated with adolescent turmoil—rebelliousness, conflict with parents and authority figures, negativism, impulsivity, tension, mood swings, and vacillation in goals and plans. In some cases these phenomena were symptomatic of definite behavior disorder; in other instances they occurred in youngsters who were coping effectively and constructively with the demands of the adolescent period and who did not show clinically significant psychopathology. Other adolescents who were also coping and developing on a healthy level showed no evidence of turmoil. Finally, some of the behavior problem group with symptoms in the direction of passivity and inhibition of functioning also had few or none of the characteristic manifestations of turmoil despite their clear-cut psychopathology and disturbed functioning. It is our impression that these differences may be related at least in part to individual patterns of temperament, although our data analyses are still incomplete in this regard. It will also be of interest to determine what correlation, if any, exists between the presence or absence of adolescent turmoil and psychological functioning in early adult life.

In any case, the evidence from this group of adolescents indicates that no a priori conclusion can be drawn as to the significance of the presence or absence of adolescent turmoil in any specific youngster. Each case has to be evaluated individually and in the perspective of overall behavior and functioning.

In reviewing the sequential histories of our study population we have found it most fruitful to view adolescence as a qualitatively new stage of development, in which the youngster faces new demands, expectations and issues, and to which he brings to bear his past experiences and characteristics and his new physiological, cognitive, and emotional capacities. Psychological development always represents a continuously evolving individual-environment interactive process, with qualitatively new elements in both the individual and the environment introduced at all sequential age-stages. This is especially true in adolescence, when there is a dramatic combination and interplay of the old and the new in psychological development.

The Role of Neurosis in Phylogenetic Adaptation, with Particular Reference to Early Man

BY LEON SLOMAN, M.R.C.S., L.R.C.P.

The author hypothesizes that neurosis results from maladaptation and leads to further maladaptation, thus creating a vicious cycle that can be viewed as having played a significant role in human evolution. Individuals who were less successful in the struggle for survival during prehistory would have been more likely to become neurotic, a maladaptation that would magnify existing genetically transmitted differences in their viability and affect both the choice of a mate and the viability of their offspring. This process would have accelerated human evolution by favoring the most viable. The author relates this theory to his concepts of assortative mating and to other theories of the role of neurosis.

CURRENT THEORIES about the biological role of neurosis tend to be mutually contradictory and offer only partial explanations. One of the central issues is whether or not an adaptive or maladaptive role should be attributed to neurosis.

As a result of Freud's influence, clinicians tend to see neurotic symptoms as having a positive function, that of providing solutions to problems that otherwise seem insoluble. We postulate that this source of satisfaction is what allows them to persist for long periods almost unabated. In clinical practice, we tend to focus on the adaptive and compensatory components of neurosis. However, patients seek help because of symptoms of anxiety or depression, which they view as clearly maladaptive.

Within a psychodynamic framework, one can delineate a snowball effect in psychoneurosis whereby maladaptation leads to further maladaptation. For example, problems in the oedipal phase may contribute to subsequent problems in obtaining satisfaction of affectional needs or in productively harnessing aggressive drives. Alternatively, adaptive failures at a later age can lead to regression to earlier fixation points, which may precipitate neurotic symptoms and thereby compound the initial maladaptation. The view taken within this formulation is that neurosis results from maladaptation and then causes more maladaptation.

Dr. Sloman is Assistant Professor, Department of Psychiatry, University of Toronto, and Senior Psychiatrist, Clarke Institute of Psychiatry, 250 College St., Toronto M5T 1R8, Ont., Canada.

The author wishes to thank Dr. Mary Konstantareas and Dr. Robin Eastwood for their help in preparing this paper.

Referring to neurosis, Gantt (1), a noted experimenter in the area of animal neurosis, commented that "maladaptation is as inherent in the physiology of the organism as is adaptation and, like adaptation, it has its basis on physiological structures." Gantt implies that maladaptation is an active process. It is easier to reconcile the concept of active adaptation than that of active maladaptation with what we know of biological function; Gantt's concept of active maladaptation may therefore be difficult to understand. In this paper, I will present a hypothesis to explain how individual maladaptation could have played an adaptive role for the human species. I will introduce the discussion by describing what I mean by the terms "maladaptation," "adaptation," and "neurosis" and presenting a brief summary of the theories that try to account for the maladaptive role of neurosis.

DEFINTION OF ADAPTATION AND MALADAPTATION

Adaptation has many meanings (2); here, it is used in a phylogenetic sense. The definition of natural selection as differential reproductive success between contemporary genetic alternatives implies that adaptation demands the historical context of becoming and cannot be discussed in absolute terms.

Maladaptation is a concept diametrically opposite to adaptation, but I will introduce an additional distinction in this paper. Whereas I will use a phylogenetic concept of adaptation, the term maladaptation will be used in an ontogenetic context. Maladaptation would therefore be likely to diminish the likelihood of reproductive success as well as the individual's ability to discharge his responsibilities toward himself and other members of the group. For example, maladaptation may hamper functioning within both the mating role and the parental role. This use of the term maladaptation (because of the inapplicability of the term natural selection, as discussed below) is not readily applicable to modern Western society. As is argued below, the series of individual maladaptations is seen as promoting the phylogenetic adaptation of the species as a whole.

NEUROSIS

Estimates of the prevalence of psychoneurosis in the general population vary with methodology and

diagnostic criteria. One study suggested a figure of about 20% (3). Although there has been some question as to whether experimental neurosis in animals meets the criteria of neurosis as set by clinicians (4), lower animals also seem to be susceptible to stress (5, 6).

There is evidence that neurosis is disadvantageous to man; individuals diagnosed as neurotic have been found to have a greater incidence of physical illness (7, 8) and higher mortality (9). Hinkle and Wolff (10) demonstrated that man develops illness most frequently at those times when he is having the most difficulty adapting to his environment. These illnesses tend to occur in "clusters," each of which consists of a variety of illnesses involving several body systems. They argue that "Man's relation to his social environment has relatively small influence upon the form which illness takes, but it has a major influence upon the time and the situation in which illnesses will occur and the course which they will pursue."

One might say that man has a generalized psychophysical propensity to disease (7). The greater the difficulty in adapting to the social environment, the more severe the illness, be it neurotic, physical, or both. This vicious cycle of neurotic maladaptation (which may extend to physical disease) will be discussed below.

Definition

I will use Hebb's definition of neurosis as an "undesirable emotional condition which is generalized and persistent . . . occurs in a minority of the population and has no origin in a gross neural lesion" (4). I will interpret "undesirable emotional condition" as referring to patterns of anxiety and depression without (in the interest of brevity) attempting to clarify the distinction between neurosis and psychosis. This definition will exclude the adaptive reactions of personality to anxiety or depression.

Current Theories of Neurosis and Adaptation

Prima facie, maladaptive behavior cannot be adaptive, yet neurotic maladaptation is very common in our society. This problem has challenged theorists. Jonas and Jonas (11) interpreted neurotic behavior as an "archaic response" and attributed a purely vestigial role to it. It is difficult to reconcile this hypothesis with the prevalence of the so-called vestigial phenomenon of neurosis. Clearly, if neurotic behavior were vestigial, it should occur very infrequently.

Barnett (12) proposed a relationship between psychoneurosis and psychosomatic disorders in man and "displacement behaviour" in animals, thereby implying no specific adaptive or maladaptive role for neurosis. Price (13), however, believed that neurosis could play an adaptive biological role. Although he viewed human neurotic reactions characterized by depression, anxiety, and lack of self-confidence as painful and incapacitating, which implies a maladaptive function, he hypothesized that they evolved as the "yielding" component of "ritual agonistic behaviour." Agonistic behavior covers all aspects of conflict between members of the same species, including threat, fighting, domination, submission, and retreat. Ritual agonistic behavior is designed to achieve the settlement of a dispute by an exchange of signals rather than blows (13). Because it avoids combat, yielding behavior apparently prevents unnecessary injuries or fatalities. Frank (14) also claimed that depression can play a biologically adaptive role, but he attributes this to the function of depression as a means of conserving energy.

Rodger (15) suggested that depression may be a biological mechanism for preventing incapable and rejected members from rejoining their herd. He thus views depression as maladaptive for the individual but adaptive for the group as a whole.

Although none of these theories is sufficiently comprehensive to explain the biological role of neurosis, neither Price's nor Rodger's theory is incompatible with the hypothesis I will advance below.

VICIOUS CYCLES OF MALADAPTATION

The view that neurosis results from maladaptation and leads to further maladaptation is basic to my theory. This vicious cycle operates in a situation where the inability to cope leads to anxiety, which compounds the person's difficulty in coping. A depressive vicious cycle may also manifest itself when repeated failure leads to a loss of initiative and drive, with feelings of hopelessness and helplessness that make further failure inevitable.

In behavioral studies, it has been demonstrated that increasing anxiety or "arousal above the optimal condition" leads to a deterioration in performance on certain tasks (16, 17); this is what happens in chronic psychoneurosis. Anxiety has also been shown to reduce the ability to improvise responses, which is likely to make adaptation more difficult (18). Inability to cope may therefore eventually lead to excessive "arousal," which results in greater maladaptation, creating a vicious cycle.

In order to understand the neurophysiological basis of this vicious cycle, one can refer to Hill (19), who differentiated two physiological patterns: a state of arousal experienced by the patient as anxiety or tension, and a state of "inhibition" or "depression-withdrawal." Hill noted that "both inhibition and arousal coexist in many patients and that inhibition is not merely a function of low arousal." It is interesting that this hypothesis was suggested in part by research evidence that inhibition may be an active process (20).

Furthermore, Malmo (21) described the concept of "behavioral arousal," which he related to psychoneurosis and anxiety. According to Malmo, chronic anxiety is a "disease of overarousal" or, in Selye's terms (22), a "disease of adaptation." The critical neural change is thought to be produced by a process of attrition from excessive and extended overarousal.

THE HYPOTHESIS

The biological mechanisms I will describe below are thought to have operated in prehistoric times and to probably no longer play any very significant evolutionary role. As Huxley said, "The human situation is so different from the biological, that it may prove best to abandon the attempt to apply concepts like natural selection to modern human affairs" (23). Therefore, one cannot rely too much on direct clinical observations to evaluate the validity of these theories.

According to the theory of natural selection, differences in viability between competing members of a group influence their relative chances of survival. If the genetic differences in viability are extremely small, they would have only a limited differential impact on the chance of survival.

My hypothesis is that those who were less successful in the competitive struggle for survival were likely to become more neurotic. According to this hypothesis, neurotic reactions represented maladaptive vicious cycles, which would have led to a magnification of small existing differences in viability. This would have accelerated the rate of human evolution in the prehistoric era.

It is thought that neurotic maladaptation results from the interaction between the individual and his environment. In primitive human societies, where there was an active struggle for survival, the less successful groups or group members were more prone to develop neurotic maladaptive patterns. As a result, those humans who were less viable due to genetically determined weakness in given areas relative to given environmental demands would have suffered from a greater degree of neurotic disability. In this neurotic vicious cycle, those who were least fit genetically would have been more rapidly eliminated in the struggle for survival. Although this mechanism would have been disadvantageous to some, it could have been advantageous to the survival of the group as a whole. The more active elimination of those who were least fit genetically would have resulted in increased genetic fitness in the surviving members. In this way, a small genetic difference between competing members of a group could have had a major impact on their relative chances of survival. Neurotic maladaptation could therefore be viewed as a mechanism that greatly accelerated the evolution of particular groups and of the human species in general by favoring the survival of the most viable individuals among early man.

GROUP SELECTION

If the potential to develop neurosis can only operate to the disadvantage of the individual, one might expect this potential to be eliminated by natural selection. How then is it passed on? This question could be answered by the concept of group selection (24, 25). Wynne-Edwards broke natural selection down into several categories that are functionally as well as conceptually distinct. He proposed the concept of group selection, which operates through success or failure of entire groups of individuals. Simply stated, this is natural selection operating at the group level. He feels group selection does no more than "correcting in part . . . the shortcomings of individual selection from the standpoint of the species as a whole." Whereas all members of the group have the potential to develop neurotic maladaptive patterns, only some would actually do so. This mechanism would have aided the survival of the group as a whole by accelerating the process of natural selection, which would lead to a more rapid adaptation of the group members over a period of generations.

In Darwinian natural selection, the most viable member of the group is likely to have the largest number of descendants and the least viable few or none. I propose that natural selection was accelerated by the following mechanism. Those who were less successful in the competition for survival were likely to become more neurotic. The experience of failure results in decreased self-esteem, feelings of inferiority, and reactions of anxiety and depression, characterized by indecision, hesitancy, and lack of confidence. According to this theory of neurosis, the severity of neurosis in prehistoric society would have been a rough index of the degree of maladaptation of the individual.

As the competitive struggle for survival led to the less successful members becoming more neurotic, there was a vicious cycle wherein the less viable developed maladaptive reactions, which led to further failure, resulting in even greater anxiety and depression. Faster elimination of those who were genetically less fit would have led to a more rapid spread of positive genetic mutations.

I will use as an example a group of Ojibway Indians before the advent of the white man whose survival depended on their success in hunting and trapping in a period of food shortage. One adolescent member of the group is a little more skillful than his peers. His success wins him general approbation and his parents feel proud of his achievements. This young man develops what Erikson termed a "sense of mastery" and a strong positive "sense of identity" (26). He will be labeled as "highly viable and minimally neurotic." By contrast, one member of the group is conspicuously unsuccessful. He becomes an object of derision and develops strong feelings of inferiority and a sense of identity diffusion. He will be labeled as having "low viability" and being "highly neurotic." One can examine the probable outcome of this situation in light of the different theories.

According to the theory of natural selection, the ability of the most viable member of the group to find food would have increased his chances of survival and vice versa. However, if the group of Indians shared the small amount of food that was available (as was probably the case), the variation in hunting skills might

have had little or no impact on differential chances of survival.

According to the theory of neurotic maladaptation, the most viable and therefore least neurotic member of the group would have had an added psychological advantage over his peers in the competitive struggle for survival. The least viable and therefore most neurotic member would have been at a particular disadvantage. His neurosis would have handicapped him in the struggle for survival by lowering his adaptive efficiency and increasing his predisposition to illness. His neurosis would also have influenced him in his selection of a mate, as will be described below.

NEUROSIS AND ASSORTATIVE MATING

The theory I have described dovetails with a theory of assortative mating that I have explained more fully elsewhere (27). In order to demonstrate this interrelationship, I will give a brief outline of that theory.

I have argued that the degree of neurotic maladaptation was at one time an index of environmental maladaptation. Neurosis is characterized by anxiety and depression, which can influence the attractiveness of personality, poise, and appearance. It has also been said that neurotics marry other neurotics (28). These ideas have been incorporated into a theory about the evolutionary role of human assortative mating. The theory states that assortative mating is a mechanism that, in ancient times, favored the mutual selection of those who were more viable. According to this theory, the most viable and least neurotic members found each other more attractive and chose each other as mates. This would have led to a segregation of "more viable" genes from the "less viable." As a result of assortative mating, the strong members united so that they in effect became stronger and the weak became weaker. By this mechanism, the genetic differences that already existed would have been increased.

Whereas neurotic maladaptation would have contributed to the elimination by natural selection of those who were less fit, assortative mating would have increased the differential advantage of the strong. The mechanisms of action of neurotic maladaptation and assortative mating would have been closely interrelated. Through their combined effect, they would have greatly accelerated the action of natural selection and thereby accelerated the rate of human evolution.

The relationship among neurosis, assortative mating, and viability can be illustrated by the use of the term "impotent." Impotence is often a manifestation of neurosis and obviously leads to problems in selection of a mate. The term also refers to an inability to master difficult situations. This linguistic linking of general ability, neurotic problems, and sexual ability might reflect the biological link that I am proposing.

Parents who are poorly endowed genetically are likely to have children who are also genetically handicapped. In addition, parents transmit neurotic patterns to their progeny by direct interaction (29). The descendants of those who are most viable will have multiple advantages. They will be genetically well endowed, less neurotic, and will enjoy a strong advantage in the struggle for survival.

To return to the example of the Ojibway Indians, the highly viable and minimally neurotic member would possess the poise, serenity, and other criteria of attractiveness that would lead to his mating with an attractive female, who would also be highly viable and minimally neurotic. The highly neurotic group member of low viability would be likely to select a very neurotic partner of low viability.

The descendants of neurotic individuals of low viability are at a disadvantage both genetically and because of being highly neurotic. Therefore, one might expect their strain to die out. Conversely, the descendants of the most viable individual, who would be minimally neurotic and highly viable, should continue to multiply.

ADDITIONAL ASPECTS OF THE HYPOTHESIS

The mechanism of neurotic maladaptation would have particularly favored the evolution of the most complex structures, such as the brain. Chance mutations with a favorable influence on man's intelligence were probably rare and of minuscule effect. However, as a result of the long-term interaction between competing individuals, these small differences could have led to the development of a maladaptive vicious cycle in the less well-endowed individual. Neurotic maladaptation would in this way have specifically increased the impact of these small genetic differences. This process would have greatly accelerated the evolution of man's intelligence. There is considerable ethological data to support this theory—these data have been summarized elsewhere (30). However, my main interest is in clinical implications (31).

Whereas the focus of this paper has been on a negative concept, namely neurotic maladaptation, I might point out the positive aspect of healthy adaptation (using the term now within the context of emotional maturity) as did Saul (32) in his description of the mature personality: "Freed from childhood patterns, he is discriminating and highly adaptable. And, among the many results of such development, his anxiety is at a minimum." Achievement of emotional maturity could be seen as a response that would have greatly aided the struggle for survival. Today, it might be seen as a way of making that survival more meaningful.

Principles of the New Sex Therapy

BY WILLIAM H. MASTERS, M.D., AND VIRGINIA E. JOHNSON

The authors review the development of their rapid treatment dual-sex therapy for sexual dysfunction. The basic tenets of the new sex therapy include 1) sound knowledge of physiology, endocrinology, and metabolic function, 2) institution of psychotherapy only when organic factors have been identified or ruled out, 3) treatment of the couple as a unit by dual-sex therapy teams, 4) a short-term intensive program, and 5) education in techniques of verbal and nonverbal communication. Since its inception in 1958, the new therapy has been adopted, modified, and examined by clinicians and researchers all over the world. The authors suggest that professionals interested in effective treatment for sexual dysfunction should improve techniques, train personnel, and encourage sound research.

SINCE THE PUBLICATION of *Human Sexual Inadequacy* (1) in 1970, there have been many attempts by other health care professionals to interpret and extend the original concepts of dual-sex psychotherapy for the rapid treatment of sexual dysfunction. As part of the original research design, the Reproductive Biology Research Foundation has continued to reexamine its own philosophy and treatment methodology subsequent to further clinical experience, additional follow-up information, and constructive criticism from other sources. Although such an evaluation process might be expected to lead to broad changes in methodologies, the foundation's basic conceptual framework for treating sexual problems has not substantially altered. In view of the increasing clinical interest in both the theory and practice of therapy for sexual dysfunction, a glance at the original treatment tenets from a current perspective may be of interest.

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are the Co-Directors of the Reproductive Biology Research Foundation, 4910 Forest Park Blvd., St. Louis, Mo. 63108.

SEX THERAPY IN 1958

In 1958, as we began to make plans for a clinical research program in the psychotherapy of human sexual dysfunction, we conducted a detailed review of existing methods and findings in the field. It was immediately apparent that the available research was fragmented and unsystematic, with a marked dichotomy between biological and behavioral data that reflected the scientific bias of the times. Clinical techniques were both time-consuming and unreliable, and there were many indications that these methods derived more from the therapist's personal investment in the psychotherapeutic process than from an objective knowledge of sexual function or a practical application of behavioral principles. Both published data and reports shared with us by people in the field clearly established the fact that health-care professionals were essentially ignorant not only of human sexual physiology but of the potential clinical application of such knowledge. It seemed that sexually dysfunctional patients were being treated with professional insight drawn either from the psychotherapist's own sexual experience—good, bad, or indifferent as it may have been—or from anecdotal material provided by previous patients.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editor considers this material to constitute a comprehensive analysis of the topic.

This perspective was even bleaker when viewed within the constraints imposed by unrealistic dogma and prevailing modes of psychotherapy that peremptorily dismissed any nontraditional approach as worthless. Given this situation, innovation appeared to offer at least a realistic chance to improve treatment efficiency and efficacy. To assess this potential, we felt it necessary to document extensively the effectiveness of our experimental therapy model along at least two dimensions—the number and diversity of cases treated and the duration of therapy follow-up. Therefore, the research format that was implemented in 1959 included a plan to gather five-year follow-up data on treatment outcome.

Simply stated, the research was designed to evaluate a two-week intensive psychotherapeutic approach to sexual dysfunction working in a format that examined the psychological and social components of sexual dysfunction along with the organic factors involved. This rationale was based on recognition of the fact that contemporary social values and pressures interact with individual sexual attitudes, experiences, and feelings derived from the past, and that no better microcosm of these elements could be found than a relationship in which one or both partners were sexually distressed. To ignore the relationship seemed not only to deny the importance of a partner's potential positive or negative contribution but also to waste an opportunity to investigate the social laboratory provided by the relationship.

ORGANIC ASPECTS OF SEXUAL DYSFUNCTION

At the outset, it seemed logical to assume that a thorough knowledge of male and female pelvic anatomy, endocrinology, and metabolic function would be a strong asset in any approach to the treatment of sexual problems. This scientific background seemed essential for accurate evaluation of the organic aspects of sexual dysfunction; it also offered an opportunity for enhancing the psychotherapeutic process by providing a factual data base from which questions on sexual physiology could be answered objectively. It has become increasingly apparent that such expertise also provides therapists with objective criteria for assessing the dimensions of clinical progress, both psychological and physiological, during the treatment process. Detailed knowledge of anatomy, physiology, and metabolic function will never replace the skills of a well-ordered and sensitive psychotherapeutic approach to sexual dysfunction, but neither can therapists realistically continue to ignore these areas in the psychotherapeutic process.

It is important that prompt and thorough assessment of the organic aspects of sexual problems be carried out prior to treatment. Approximately 5% of all cases of sexual dysfunction are of physical origin and a higher but undetermined percentage are of metabolic origin; thus psychotherapy should not be instituted until the possibility of organic etiologies of sexual distress has been either eliminated or identified and treated when necessary. It is just as unconscionable to treat sexual distress of metabolic or physiological etiology exclusively with psychotherapy as it is to treat a psychosomatic illness directly with surgery. In 1958 patients with complaints of sexual dysfunction were rarely checked as thoroughly as possible, either physically or metabolically, before psychotherapy was initiated. Unfortunately, comprehensive assessment of these factors before a commitment to long-term treatment is still far from routine.

LEARNING AND INSTINCT

An original and continuing premise of our treatment model is that sexual response is a natural function. Human sexual behavior is clearly a complex set of learned and instinctive phenomena interacting with personality dynamics, hormonal factors, and cultural influences. Penile erection and vaginal lubrication are just as clearly inborn reflexes, not learned behavioral responses. Just as the natural physiological functions of respiration, digestion, and urination are not taught to the newborn infant, the reflex pathways of sexual response cannot be taught. Sexual functioning is influenced by psychosocial input, just as other natural physiological functions are, and can be disrupted by anxiety, depression, or physical stress.

A major misconception that was at one time shared by patients and health care professionals was that sexually dysfunctional individuals can be taught to respond effectively (i.e., the impotent male can be taught to achieve erections or the sexually dysfunctional woman can be taught vaginal lubrication). This is like believing that we can be taught how to sweat or to make our hearts beat. Certainly, we do learn the behavioral aspects of any natural function. Because sexual functioning involves social as well as psychophysiological components, we must emphasize learning as it relates to sexual behavior, but our potential to respond to effective sexual stimulation is instinctual rather than learned. This does not mean that we cannot learn ways of facilitating our biological potential; unfortunately, it also implies that we *can* learn ways of disrupting our natural physiological processes.

Many individuals seek counseling on the assumption that there are reliable methods of teaching sexual response. This is not quite accurate. What does exist is the possibility of identifying the obstacles to effective sexual functioning that have removed sex from its natural context and suggesting ways to alleviate and/or circumvent these obstacles. Similarly, attitudes, behavior, and emotional environments conducive to individual sexual response can be identified and encouraged. When this is done, natural function usually takes over with surprising ease. This is one of the reasons why a brief but highly concentrated form of psychotherapy can be very effective in treating sexual dysfunction.

THE COUPLE AS THE UNIT

Another reason for the effectiveness of short-term intensive therapy for sexual dysfunction that was also among the original treatment tenets stems from the emphasis on the couple—the contention that there is no such thing as an uninvolved partner in any committed relationship where there is sexual dysfunction. This partnership component of sexual functioning would seem obvious; however, the frequent use of individual psychotherapy indicated that the importance of mutual involvement in the problem was not always fully appreciated. In our nontraditional methodology, we felt it was imperative to direct treatment to the education of both partners simultaneously rather than focusing exclusively on the sexual distress of the chief complainant.

We were particularly concerned about the established practice of sending marital partners to separate therapists, especially when husband and wife individually described separate sexual dysfunctions. When two marital partners, each with his or her own sexual dysfunction, are treated by different therapists with different professional orientations, professional capacities, and levels of interest in and knowledge of the field of sexual response, the chances of returning effective sexual response patterns to the marital partners individually or to the marital relationship are negligible.

This principle of involvement of both partners has been widely misinterpreted. No implication of causality is necessarily intended—it is often apparent that the genesis of one partner's sexual difficulties antedated his/her entrance into the relationship that presents for treatment. Alternatively, when sexual problems arise for the first time in a relationship where there had previously been satisfactory sexual interaction, the dysfunction often arises from circumstances that are totally unrelated to the functional partner. However, the functional partner is certainly involved in the problem to the extent that he/she may experience sexual frustration, disruption of other areas in the relationship, and reverberations in occupational performance, social patterns, and self- or partner deprecation.

THE DUAL-SEX THERAPY TEAM

A psychotherapeutic format using a male and female cotherapist team seemed particularly indicated in the treatment of the sexually distressed. Men generally have a limited experiential frame of reference from which to identify with female sexuality and have essentially no concept of the subjective aspects of female sexual function. Women often do not fully comprehend the subjective aspects of male sexual functioning or empathize with the depth of most men's ego involvement with their sexuality. A man simply does not know what woman's orgasmic episode feels like, and a woman will never experience the ejaculatory process. Neither sex finds it easy to evaluate for the other the relationship between effective sexual function and sexual identity.

Earlier therapeutic techniques often failed to produce the desired return to effective sexual function because the therapists (most of whom were men) simply presumed expertise in both the sexual function and the sexuality of the opposite sex. As we gain knowledge of male and female sexuality and as our experience with the basic science aspects of human sexual function increases, it is to be hoped that specific gaps in our appreciation of the sexual response patterns of the opposite sex will be reduced. However, in 1958 we had—and unfortunately we still have—no real concept of the depth of general ignorance of the sexuality and the sexual functioning of the opposite sex.

Another advantage of the dual-sex team is related to the tendency of therapists to inadvertently impress their own social or sexual value systems on sexually distressed patients. The dual-sex therapy team is, in theory, an excellent counterbalance to this unfortunate therapeutic tendency. A primary function of the team is to acquire knowledge of the sexual value system of each marital partner by careful interview techniques. The basic therapeutic approach is then to encourage the couple to achieve their mutual sexual goals and to identify and enjoy their own concepts of satisfying marital interaction rather than the therapists' suggesting or impressing their own social or sexual value system in the treatment. If each partner's goals can first be understood and appreciated by the therapists and can then be explained to both partners, the committed couple will have a far better chance of attaining effective functioning.

EDUCATION

We presumed in 1958 on the basis of 13 years' experience in working with problems of infertility that simple education of patients in the factual anatomy and physiology of human sexual response might, in some instances, relieve a significant amount of sexual dysfunction. Certainly, the practice of seeing the partners in a distressed sexual relationship as a couple rather than as separate individuals has enabled us to educate patients more effectively. In this context, when a couple is treated for sexual distress, the learning opportunity becomes a combination of individual gain and mutual enrichment. Rather than just learning of self, a man and a woman treated together have the opportunity to consider the dynamics of their relationship. Man learns of woman as woman learns of self and vice versa. This mutual educational opportunity is particularly effective as a therapeutic procedure in dual-sex therapy, where the cotherapists can educate by modeling interactive communication, by interpreting material from both male and female perspectives, and by reinforcing therapeutic content in different individual styles and contexts.

An example of the use of simple education in treat-

ing sexual problems is our approach to vaginismus and premature ejaculation. It has long been obvious that these two problems rarely respond to specifically directed psychotherapeutic approaches. When we started developing the new sex therapy in 1958, these sexual distresses were falsely aligned with such psychosocial problems as impotence and nonorgasmic states. In fact, some psychiatric textbooks listed and defined premature ejaculation as a form of impotence. The foundation took full exception to this concept. We felt that premature ejaculation and vaginismus would respond far better to simple education of both marital partners and to the techniques of specific psychophysiological reorientation of the individual's nonproductive sexual response patterns with the partner's cooperation. There is no doubt that conditioning of reflex response patterns, usually during initial opportunities for sexual interchange, plays a major role in both rapid ejaculation and vaginismus. Therefore, specific techniques to teach partners to help each other recondition these unfortunate reflex response patterns are far more effective in reversing these distresses than any known form of formal psychotherapy.

PERFORMANCE FEARS AND THE SPECTATOR ROLE

Education is only one component of psychotherapy, and it is far more valuable when combined with some degree of insight. In treating sexual dysfunction, insight often centers on the fears of sexual performance that are inextricably woven into the genesis of sexual problems. When fear of sexual performance dominates in a relationship, either or both partners sacrifice their spontaneity as they become spectators of their sexual action. As spectators, they watch and measure their own or their partner's sexual response patterns in an attempt to overcome their performance fears by noting obvious physical signs of sexual excitation. The sexual experience ceases to be a mutually shared expression of feelings and needs and is reduced to individuals attempting to act out their expectations. The tragedy of the spectator role is that it often directly confirms the participant's worst fears—the individual or his/her partner *is* slow to respond (or does not respond at all), which confirms the spectator's feelings of sexual inadequacy. This role takes sexual response out of context and usually results in impaired function.

Neither fears of sexual performance nor the closely related spectator role has been sufficiently recognized as a primary deterrent to effective sexual functioning. In addition, the depth of male performance fears usually is not fully understood even by committed female partners, since women have had little personal frame of reference from which to appreciate the devastating effect of these fears on the male ego. Too often, a woman's well-intentioned attempt to help her sexually apprehensive partner by masking her own sexual interest tends to prevent the sexual stimulation that he might experience in response to her obvious sexual involvement.

Techniques of directly confronting fears of sexual performance and providing specific suggestions to help overcome these fears became an integral part of the new approach to sex therapy. For example, carefully structured exercises that present an opportunity to appreciate tactile sensations without any demand for overt sexual responsiveness provide one avenue for reducing cultural pressures to perform and concomitant fears of performance. Direct verbalization of these fears, both in the therapy interaction and between members of the sexually dysfunctional couple, provides another means of defusing the magnitude of anxiety because unspoken fear often looms larger than verbally acknowledged fear. Reducing the anxiety arising from self- or partner-imposed expectations for sexual performance, whether real or imagined, usually results in a move toward more spontaneous sexual interaction. Similarly, as fears dissipate, the need to be a spectator decreases and the sexual experience improves as it becomes one of involvement rather than performance.

Once either or both marital partner's fears of sexual performance have been reasonably neutralized, spectator roles can generally be easily minimized. The technique of reversing sexual dysfunction by concentrating on neutralizing performance fears and minimizing spectator roles is based on the knowledge that sexual response patterns are natural phenomena and that dysfunction of these response patterns is reversed by removing psychogenic barriers to response, not by attempting to teach the individual how to function sexually. This technique also recognizes that patterns of behavioral interaction are learned aspects of a relationship that can be modified on the basis of mutual motivation and cooperative effort.

Within this conceptual framework, it was possible to view the specific sexual dysfunction within the context of an intimate interpersonal relationship. A sexual problem may represent an isolated facet of an otherwise healthy relationship, but sexual distress usually arises from hostility, poor communication, maintenance of a double standard, unrealistic expectations, deception, differences in reproductive goals, or a host of other factors. Unless therapy focuses primarily on the relationship as a whole rather than being restricted to the sexual component, important treatment dynamics may be overlooked. For example, when a couple's system of communication is improved, the status of the relationship often stabilizes. Then, in a time frame that allows the couple to develop reasonable familiarity with the new concepts, dysfunction can often be reversed with simple educational techniques and a knowledge of the specifics of sexual physiology. Although sexual response cannot be taught, effective means of communication can be, and the newly established state of effective communication often provides a direct catalyst to the pleasurable experience of satisfying, responsive sexual interaction.

NEW SEX THERAPY COMPARED WITH TRADITIONAL TECHNIQUES

It is most important to emphasize that although psychotherapeutic dogma has been challenged in these new therapy techniques, traditional psychotherapeutic principles have not been obliterated. What has changed, of course, is the focus of therapy. Rapid treatment for sexual dysfunction emphasizes the personal interactions of men and women as they seek to enhance a total relationship rather than treatment of individuals concerned with their own sexual needs or inadequacies.

Perhaps the most significant departure from past psychotherapeutic dogma was our contention that sexual dysfunction is not necessarily a symptom of underlying psychopathology. In 1958, it was almost universally believed that if underlying psychopathology could be identified and treated successfully, symptoms of sexual inadequacy would automatically be resolved, since they were only surface manifestations of a more deeply rooted neurotic or psychotic process. We have never denied that sexual dysfunction may be a symptom of underlying psychopathology, but we do believe most emphatically that sexual inadequacy is an entity all its own at least as often as it is a symptom of severe psychopathology. This marked departure from established psychotherapeutic concepts not only encouraged the development of the rapid treatment techniques but also stimulated dissemination of the concept of sexual response as a natural function.

We also had a strong clinical feeling that when the sexual inadequacy *was* obviously a symptom of existing psychopathology, real psychotherapeutic gain might result from a direct approach to symptom removal. This position is directly antithetical to the idea that symptoms should not be approached directly because their persistence serves the useful purpose of keeping the patient in therapy. The therapy program that we developed did not ignore individual psychodynamics. Rather, it recognized that identification of factors such as stress reactions, problems of self-esteem, psychopathology, and maladaptive defense mechanisms was essential to the efficiency and efficacy of therapy.

Time Frame of the New Therapy

We presumed that there would be a number of specific therapeutic advantages to the limited time frame of the new therapy, which usually consists of daily sessions over a two-week period. First, there is significant cumulative return for patients who are exposed to sexual material on a day-by-day basis, since they become involved in mutual eroticism with increasing ease. Sexual thought and action seem to arrive at a healthy accord in a progressive manner that leads the distressed couple toward a sense of erotic well-being as a unit. Second, it is much easier to enhance communication skills when each day's successes and problems can be freely recalled and analyzed during the next day's visit. Third, it is far more clinically effective to evaluate and deal with sexual problems and questions as they develop rather than after the fact. Fourth, daily exposure to the therapists provides an ideal opportunity to handle treatment-related crises that may develop. Such crises should be approached when they occur rather than after delays of days or even weeks. When two people are involved in a treatment crisis, any delay in dealing with their distress may be disastrous.

COUNTERTRANSFERENCE ISSUES

Despite the obvious advantages of rapid treatment, we recognized that there were significant problems inherent in this mode of therapy. For example, a rapid treatment format does not allow time for the development of traditional transference interaction and insights. However, we felt that therapeutic emphasis on classical patterns of transference would obviously distract the focus of therapy from the marital relationship to the relationship between the individual and either or both cotherapists. Individuals with prior experience in analytically oriented psychotherapy often demand, overtly or covertly, a chance to nurture and discuss transference dynamics. This frequently slows progress in therapy because it diminishes the level of shared feelings within the marital relationship.

In general, the dual-sex therapy team minimizes the importance of transference. By its very design, dual-sex therapy tends to emphasize and encourage emotional identification and commitment between marital partners rather than developing the patients' emotional dependency on their therapists. It is important, however, to recognize the distinction between a full working through of transference and ways in which elements of transference phenomena can be used in particular situations.

A good example of the use of transference in the new sex therapy is the psychotherapeutic approach to vaginismus, which includes education and instruction in use of a series of vaginal dilators. It is usually necessary to foster an extraordinary degree of trust on the part of the patient toward the therapist who is performing the pelvic examinations and introducing the dilators into use. For a day or two, as the woman is gaining confidence in her ability to overcome a painful and frustrating problem, her partner's participation in the use of the dilators is typically kept to a minimum. Deliberate development of this aspect of transference has been found to be highly effective, resulting in prompt reversal of the vaginismus so that the couple can focus on their sexual interaction without fear of interference from vaginal spasms. A brief transition period is then required to downplay the transference between patient and therapist; this is usually accomplished by repeatedly stressing to the woman that *she* is the one who brought about the change and emphasizing the catalytic role played by the cotherapists.

Obviously, the therapist's authoritative position is of major import. Acceptance of authority makes the

process infinitely easier and enables it to progress with the necessary rapidity. Closely directed transference is sometimes used to set the stage for a couple to develop a more effective focus on their own interaction. Needless to say, this use of transference must be individualized. The concept of controlling or channeling transference during rapid treatment for sexual dysfunction should be seen as unique to this method; it in no sense reflects denial of the importance of the objective use of transference phenomena in other therapeutic programs.

We thought that if patients' emotional identification with the therapists (beyond that necessary to establish the authority figure) was to be discouraged, it was necessary that the cotherapist team take particular care to avoid problems arising from countertransference. The sexually dysfunctional man or woman is incredibly vulnerable to any suggestion of sexual connotation from the authority figure. Sexual seduction, whether actual or fantasized by either patient or therapist, clouds any therapeutically encouraged trend toward emotional identification within the sexually dysfunctional marital unit. Overt evidence of countertransference can create a distraction of such magnitude that the rapid treatment technique can easily be prejudiced.

We have seen direct evidence of the ultimate in countertransference many, many times in histories of patients who had other types of psychotherapy for sexual dysfunction before considering dual-sex rapid treatment techniques. The ultimate in countertransference is, of course, a therapist seducing a patient into overt sexual activity. We feel that this approach to the extremely vulnerable patient with a dysfunction is professionally and personally inexcusable. The use of dual-sex teams provides a significant degree of built-in protection against any extensive devlopment of countertransference, much less seduction of patients.

We feel that when sexual seduction of patients can be firmly established by due legal process, regardless of whether the seduction was initiated by the patient or the therapist, the therapist should initially be sued for rape rather than for malpractice, i.e., the legal process should be criminal rather than civil. Few psychotherapists would be willing to appear in court on behalf of a colleague and testify that the sexually dysfunctional patient's facility for decision making could be considered normally objective when he or she accepts sexual submission after developing extreme emotional dependence on the therapist.

PEER REVIEW

Peer review is an integral part of patient care, and self-regulation certainly has been established and supported by the medical fraternity. There is, however, a lack of peer review for psychotherapists of any persuasion in the private practice of their art; not only has this been a major handicap to the therapist professionally but also an obvious obstacle to good patient care. There is currently less peer review of professional productivity in psychiatry than in any other major discipline in medicine. Once a psychotherapist has completed training, his or her work is rarely if ever subjected to peer review. This clinical tragedy slows and may prevent professional growth and maturity. Inevitably, it is the patient who suffers.

We believed that a dual-sex therapy team would provide a built-in opportunity for a modest degree of continuing peer review, since the members of the team would be immediately accountable to each other. While we did not consider this approach to peer review completely satisfactory, and did not feel it should be employed to the exclusion of formalized peer review programs, we did think that objective criticism from a co-therapist was far better than any self-review technique imaginable.

IMPROVING COMMUNICATION WITHIN THE COUPLE

Satisfying sexual interaction has always represented a mutually enhancing means of communication between man and woman. When sexual interaction is not initiated merely for the release of accumulated sexual tensions, what is its potential? As a means of communication, its potential is vast. In one important dimension, sexual communication can be viewed as the medium or opportunity for exchanging trust and vulnerability. Sexual interaction represents a uniquely vulnerable occasion for committed participants on both a physical and an emotional level. Within this framework of sex as a form of communication, we decided to concentrate much attention on developing techniques to improve intimate communication skills. We presumed that if effective communication were established outside the bedroom and sexual anxieties were reduced, sexual functioning would often improve. This presumption has certainly been supported by our clinical experiences of the last 18 years.

Sensate Focus

Our original approach was to focus on the nonverbal aspects of communication. Because the sense of touch is most identified with nonverbal communication and is the special sense used most often in sexual interaction, we developed the concept of sensate focus.

In order to achieve optimum effect, sensate focus should be used as a means of physical awareness by the partner doing the touching and not specifically or solely for the sensual pleasure or even sexual excitation of the partner being touched. Sensate focus in the early stages of therapy tends to dissipate anxieties related to sexual performance on the part of either or both spouses. Thus, in nonverbal communication, the therapeutic emphasis is on touching as a personal sensual experience and only secondarily, if at all, as a sexual opportunity. The sensual experience consists of exploring the textures, contours, temperatures, and con-

trasts of the partner's body in a manner and at a pace chosen by the individual doing the touching. By specifically structuring the sensate focus opportunities at the onset of therapy, it is usually possible to significantly reduce the constraints imposed by old habit patterns of sexual interaction. Concomitantly, removing stereotyped expectations of what sexual interaction "should be" often leads to an awakening of spontaneous natural response that has long been forgotten and sometimes never recognized.

We have noted with regret that the technique of sensate focus has been introduced out of context countless times by therapists and has been used indiscriminately as a means of sexual stimulation, even in public settings where the individual's sexual response has little opportunity of being supported by fulfillment of related needs. In these cases, the specifically designed function of self-awareness in the use of touch as an excellent means of initiating nonverbal communication usually is lost.

Verbal Techniques

Verbal communication, although often emotionally charged in a couple with sexual problems, is more familiar and thus more comfortable than nonverbal communication for many individuals. Because of this, a significant focus of the new therapy was education in more effective verbal communication. Many couples are surprised that the majority of time in therapy is devoted to this area. It is indeed dramatic to find how often improvement in verbal communication skills releases a couple's sexual feelings toward one another and thereby enhances their sexual relationship.

Isolation During Therapy

We felt that a period of uninterrupted attention to the relationship was necessary to allow the couples to integrate the new techniques of verbal and nonverbal communication into the existing patterns of their lifestyle. It was anticipated that the quality of this time would be enhanced by social isolation, which would minimize interference from the exigencies of daily life. There is a decided therapeutic advantage when couples are temporarily freed from the demands of children, friends, relatives, work, and other responsibilities in a therapeutic program. This is certainly not a new concept; in fact, it follows long-proven tenets of learning theory. Once the intense phase of learning new skills is mastered, briefer exposure will suffice to maintain or improve these skills.

CONCLUSIONS

In this paper, we have briefly described the original principles of treatment that were the foundation of the new therapy techniques for sexual dysfunction. Of course, there has been both significant modification of these principles and expansion of concepts of treatment as the clinical therapy program has been closely observed during its 18 years of existence, first at Washington University School of Medicine and since 1964 at the Reproductive Biology Research Foundation.

Obviously, there have been further modifications of concept, format, and technique in various centers throughout the United States and abroad. Some have represented significant innovations and additions, others have been poorly conceived and casually conducted. All of these improvements, alterations, and even distortions simply point to the immense public demand for adequate professional support in this hitherto ignored health care field. Now that the surface has been scratched, it remains for those interested in effective treatment programs to improve techniques, train personnel, and encourage both basic science and clinical investigation.

We all have such a long way to go.

The Role of Sex Therapy in Marital Therapy

BY CLIFFORD J. SAGER, M.D.

Marital and sex therapy are clinically interrelated in most cases because they deal with different symptoms of overlapping aspects of the couple's total relationship. The connection between marital discord and sexual dysfunction determines the emphasis and course of treatment. For example, sex therapy is the immediate treatment of choice when sexual dysfunction produces secondary marital discord but not when severe discord precludes the possibility of good sexual functioning. The author presents case reports to illustrate the relationship of remote and immediate causes of marital and sexual problems and to emphasize the value of a multimodality approach to treatment.

THE ROLE of sex therapy in marital therapy has been vague and inconsistent over the past several decades. Marital therapy generally has included some sex therapy. New developments in our knowledge of the physiology of sex and the treatment of sexual dysfunctions have led to changes that can currently be described only as trends because of their newness. In this paper, I will discuss the role of the new knowledge of sex therapy as it affects marital therapy based on my experience in private practice and in a large family, marital, and sex therapy clinic and training facility.

Like the relationship between sex and marriage, the relationship between sex and marital therapy is highly complex. It would be wrong and an oversimplification to claim that sex therapy is merely a subspecialty of marital therapy. The goal of marital therapy, as I conceive it, is not simply or necessarily to make the relationship work but also to foster the growth of two individuals by harnessing the forces within the marital system and directing them toward constructive ends. Therapeutic interventions cover a wide gamut from insight-oriented interpretations to behavior modification and from individual treatment to groups and couples' groups. However, there is one common factor that categorizes all marital therapists: the use of the marital system in some conceptual and technical fashion as an integral part of the therapeutic program.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Sager is Psychiatric Director, Jewish Family Service, 33 West 60th St., New York, N.Y. 10023, and Clinical Professor of Psychiatry, Mount Sinai School of Medicine, City University of New York.

Sex therapy and marital therapy deal with different aspects of the same entity and consequently are almost always clinically interrelated. However, each has a validity of its own, rooted in its own theoretical substructure, and each employs a body of techniques that require specialized training and experience. Many clinicians see no clear-cut distinctions between sexual and marital symptoms. I have found that almost three-fourths of the couples I see have a mixture of marital discord and sexual problems in varying proportions regardless of whether their chief complaint is strictly of marital discord or of a specific sexual dysfunction. The problem is deciding when to focus on sex therapy, marital therapy, or both forms of therapy.

THERAPEUTIC FOCUS

Sex is one strand in the cable of bonding and therefore is intricately entwined with the other strands that keep the couple together and allow them to develop and grow. When several of these strands begin to fray, they must be identified and reinforced if the weakening relationship is to be strengthened. Occasionally it is only the sexual bond that needs reinforcement, in which case sex therapy is certainly the treatment of choice. More often, however, sexual dysfunction or dissatisfaction is so intimately connected with other interpersonal problems that treatment of the dysfunction alone will be of relatively little value in mending the overall fabric of the relationship. It is therefore of primary importance to be aware of the interrelatedness of the various areas of the couple's relationship and to define the connection between the sexual dysfunction and other aspects of marital disharmony.

The relationship of the discord to the dysfunction seems to be the crucial factor in determining the initial therapeutic focus in the treatment of couples with both significant marital disharmony and sexual difficulties. In evaluating the qualitative nature of the discord and the temporal relation of the dysfunction to the discord, I found that couples could be divided into three descriptive categories, reflecting the extent to which the discord causes or results from sexual dysfunction (1).

1. Sexual dysfunction produces secondary marital discord. Sex therapy is generally the treatment of choice in this situation, especially when the dysfunction existed before the relationship between the spouses.
2. Marital discord in other areas impairs sexual

functioning. While conjoint marital therapy may be the treatment of choice, sex therapy may be indicated if the couple's positive feelings and desire to improve their marriage outweigh their negative feelings and the impairment in their relationship as is the case in the majority of such couples. A trial of sex therapy with these couples may result in rapid relief of symptoms and consequent increase in the self-esteem of both partners, creating a more beneficial milieu for dealing with other pressing marital problems.

3. Severe marital discord, usually with basic hostility, precludes the possibility of good sexual functioning. Immediate sex therapy would be contraindicated in this situation, since the couple's hostility would not allow them to attain the level of cooperation necessary for the rapid treatment of their dysfunction.

While extreme hostility augurs poorly for sex therapy, it is not a deterrent to marital therapy provided there is a genuine desire on the part of both partners to improve their relationship. After or during this improvement, more direct sex therapy may be initiated.

The couples model developed in marital therapy and applied by Masters and Johnson (2, 3) to sex therapy has been fed back into the mainstream of psychiatry by Kaplan's delineation of sexual dysfunctions as psychosomatic disorders (4). Kaplan elaborated a multicausal theory of the sexual dysfunctions, separating immediate forces in the couple's interactions that contribute to malfunctioning from etiological factors based on earlier experiences that predispose the individual to be dysfunctional. Sexual dysfunctions are not necessarily caused by deep intrapsychic problems that reflect disturbance in gender identity or unconscious conflicts. Most symptoms have multiple determinants. Often the sexual malfunction results from the couple's specific interaction, which may then serve as the overdetermining factor to produce symptoms (immediate cause) in an individual made susceptible by remote causes. The person without a partner often cannot be treated as effectively for a sexual dysfunction because the therapeutic leverage of interactional factors can be used only when an involved partner participates in the treatment program (5).

The recognition that the immediate cause occurs within a susceptibility diathesis due to remote causes within the person has important theoretical and clinical implications. It provides the theoretical rationale for combining task-oriented therapy with other treatment methods based on the therapist's knowledge of the remote etiological factors. The remote causes may be bypassed but not ignored by the therapist.

The terms used to describe intrapsychic pathology often carry questionable value judgments as, for example, in a situation in which a wife's transactions with her spouse appear to "cause" his impotence; the woman is often labeled as castrating, while the man may be described as weak, dependent, or passive. These adjectives are grave indictments of both partners' intrapsychic structure. However, impotence may also be conceptualized as resulting from the quality and content of an interaction at a particular time. No negative character traits need be involved; the man may not be weak, dependent, or passive in his general conduct, and the wife may not have a need to control or humiliate her husband. We may then expect that the impotence would respond to forms of treatment that will modify the couple's interactions without necessitating long-term therapeutic efforts to change their individual intrapsychic structures. This approach is quite different from that which might be undertaken when the therapist is skilled only in individual insight and conflict resolution modalities.

RELATIONSHIP BETWEEN MARITAL AND SEX THERAPY

The task-oriented, symptom-removal approach in marital therapy has been given much impetus by our having witnessed its effective use in sex therapy. For example, the use of erotic tasks in sex therapy has encouraged us to use tasks in marital therapy. I am currently applying this approach within the systems treatment model concept of the marital pair.

Treatment is facilitated when both marital and sex therapy are readily available to couples, regardless of their chief complaint, as is the case at the Jewish Family Service Clinic. Professionals competent in both marital and sex therapy increasingly appreciate that we cannot always focus simply on brief sex therapy and must be more flexible about length and type of treatment. There must often be a significant amount of time allotted to marital therapy within the context of the sex therapy program, particularly if the interaction between the partners is not consistent with the prerequisites for sex therapy. When sex therapy has been initiated, the therapist must be cautious of the tendency to regard the upsurge of conflicts in other areas of the marriage merely as indicators of resistances to treatment of the sexual dysfunction. The emergence of such marital conflicts may indeed signal resistance, but it may also be a valid indication for referral or for increased emphasis on marital therapy.

I do not think of sex and marital therapy as two isolated specialties that view the couple from different perspectives. Both try to examine and affect the same system of two persons. Hence, the sex therapy specialist must also be a well-trained marital therapist who is able to bring interactional and intrapsychic as well as sexual problems into focus. Conversely, the specialist in marital therapy must feel comfortable and competent in dealing with his patients' sexual problems. The marital therapist's attainment of some competency in sex therapy (and vice versa) need not preclude referral to experienced specialists when he knows he is getting beyond his expertise or into areas that he is not comfortable with or interested in.

In my first published opinion on this issue (1) I stated definitely that the therapist who is qualified to use both marital and sex therapy should keep the two

sharply separated. With additional experience, I have become less rigid. The interplay between immediate and remote causes often requires a frequent shift of therapeutic emphasis. However, both the therapist and the couple should know when the focus is on sex therapy and when some remote factor dealing with hostility or trust has to be explored before one can risk changing their behavior.

The important principle is that a couple's sexual functioning is only one aspect of their total dyadic system. It is readily influenced by and in turn readily influences other functions and processes. The therapist can feel free to move between the special techniques of each modality while appreciating that he is always working with numerous interrelated functions. Failure in one area may deeply affect other functions.

The presenting problem of many couples is such that rapid treatment of sexual dysfunction seems to be called for; however, more thorough examination may indicate that the problems are interactional rather than specifically sexual. The sexual dysfunction may be the sign that points to the interactional "dyscrasia." For example, the dysfunction of many couples can be best described as an infrequent desire to initiate or pursue sexual relations, a syndrome I refer to as sexual ennui. I prefer this term to "lack of libido" or "low sex drive" because it implies a psychological rather than a physical etiology or a mystical crisis of libidinal energy. When such a couple has sex, both partners may experience it as pleasurable and there may be no evidence of dysfunction. I find that treating this syndrome usually requires marital therapy in conjunction with various erotic and nonerotic tasks to be carried out at home. Treatment varies, of course, in accordance with the etiological factor(s). Often there must be several sessions focusing on the more remote aspects of the marital problem in order to achieve behavioral and attitudinal changes.

Some sex therapy techniques are very helpful in marital therapy and can be used in conjunction with more traditional techniques deriving from other schools of psychotherapy. For example, sensate focus with no genital stimulation (6) can be prescribed by the marital therapist as a way of highlighting and helping the couple work through hostilities, poor communication, fear of emotional closeness, and difficulty in verbalizing desires, and as a concrete demonstration of the importance of quid pro quo maneuvers. The procedure of taking turns giving and receiving pleasure taps deep emotional reactions in both partners. This task can be used as an evaluative test to determine several interactional and intrapsychic factors, thus helping the therapist to arrive at the most urgent and fruitful priorities for therapeutic intervention.

CASE REPORTS

I will present a few case reports to illustrate my contention that sex therapy cannot and should not be isolated from other areas of the marital system. When a sexual dysfunction is the major cause of marital discord, it may be best to focus treatment on the dysfunction—but this cannot be done in isolation from the marital interactions that have also contributed to the problem. When marital disharmony produces sex dysfunction, it is generally best to resolve some of the interactional problems first. When sexual dysfunction and marital disharmony have become a circular or reverberating system, the therapist might begin with sex therapy in an attempt to break the cycle, but he must be prepared to move freely between the two forms of treatment or to bring in another specialist if necessary.

Case 1. A woman of 30 and a man of 31 had originally been referred to me for sex therapy after the wife told her internist that, although she was orgasmic with her husband, she no longer desired sex. There was no apparent cause. I took a complete sexual history, as well as an appropriate history of their relationship. The woman was helped to appreciate her fury at her husband for what she perceived as insensitivity to her emotional needs. A short course of marital therapy, including sensate focus and other giving and receiving reciprocal tasks that were designed to increase communication and sensitivity, led both partners to an understanding of her anger and his evocative behavior, which were then modified by treatment.

The way was thus prepared for working through the immediate determinants of the woman's lack of sexual desire, which were primarily interactional. However, the wife's contribution to the couple's malfunction was also rooted in intrapsychic fears of rejection and feelings of inadequacy that she had experienced since childhood. The man's input was less specific and more reactive. Their overall relationship improved, and frequent pleasurable sex returned.

Case 2. A young couple was referred for marital therapy to the Jewish Family Service by a private psychiatrist. The caseworker who saw the couple originally felt that the wife was extremely hostile and near decompensation. A staff psychiatrist then interviewed the couple in consultation. Although the psychiatrist felt that the woman was not schizophrenic, he believed that at that time marital therapy would be too anxiety provoking for her and recommended individual treatment for the husband and wife. The husband's therapist elicited a history of marked sexual dysfunction. The wife had always been anorgasmic by any means and the husband had a history suggestive of premature ejaculation. It was also discovered that their sexual relationship was further limited by the wife's recurrent vaginal infections. A consultation with a gynecologist was arranged, and her therapist saw that she completed an adequate course of medical treatment. In the past, she had stopped taking medication prematurely and her infections then worsened. Her willingness to eradicate this physical barrier to coitus augured well for her readiness to work on her anorgasmia.

When a conference was held with all the concerned therapists, the patients also participated in the decision-making process. It was decided that individual treatment would be discontinued within a few sessions and the wife's therapist would see the couple in sex therapy, emphasizing the overall relationship problems, particularly those in the areas of trust and closeness. The wife rapidly became orgasmic by self-masturbation and by her husband's masturbation of her. His

premature ejaculation had been situational and cleared as he felt welcomed as a sex partner and respected as a person by his wife. Formal sex therapy was then stopped and the emphasis was changed, with the couple's agreement, to a new contract for time-limited marital therapy.

If this couple had continued with individual therapy instead of changing to a flexible multifaceted therapeutic approach, they would probably have proceeded to a divorce. Both partners might then have been left feeling scarred and inadequate. The case illustrates the advantages of a multimodality approach to the treatment of the total relationship.

Case 3. Two married professionals (a woman aged 26 and a man aged 30) came to therapy with a chief complaint that they were growing apart. The husband stated that he was subject to depressions that caused him to withdraw; the wife reacted to his withdrawal initially with anger and later with resignation and hopelessness. They were compatible in many areas, believed they loved one another, and wanted to make the marriage work.

When the sexual history was taken, the partners were both very definite that sex was fine mechanically; they were both invariably orgasmic during coitus. However, sex was not emotionally satisfying to the wife, and for several months prior to their seeking professional help she had allowed sex only sporadically. She had had sex with other men before marriage and with two men when she and her husband separated for a few months, and she had found that sex could be emotionally as well as physically satisfying for her. She sensed a distance between herself and her husband when they were having coitus, particularly immediately after orgasm. He would turn away and withdraw, while she wanted to snuggle and talk. "That's the time I can be most open," she said, "and he just isn't there." The husband confirmed this, describing an intolerable desire to get away after they had intercourse. He sensed her vulnerability but felt controlled and threatened by her desire for closeness.

The man's mother and father had had separate bedrooms from his first memory until he was 10 years old. During these years he slept with his mother. She was seductive toward him, which he found frightening. As an adult, he disliked and distrusted his mother and was ambivalent toward his father. His parents had a distant relationship in all aspects.

The wife had slept in the same room with her father from age 3 to age 8. Although he was seductive toward her, she recalls no actual sexual acting out. Unlike her husband's experience with his mother, she was close to her father.

Although they were both aware of these facts in each other's lives, neither had ever put these unusual "coincidences" together. The wife apparently yearned for the closeness she had or wished for with her father, and sex held no fears, anxieties, or inhibitions for her. The husband, although he did not suffer inhibition of sexual performance, experienced terrible anxiety at the prospect of emotional closeness, which was clearly related to his experience with his mother. Such a couple might provide a field day for our psychoanalytic concepts of the etiology of sexual inadequacy. Although there was no impairment of sexual functions they were as distressed about their sexual performance as other couples with actual dysfunction.

This situation required a therapist versed in marital and sex therapy and psychoanalytic psychotherapy. The therapist saw the couple conjointly to help them openly discuss their feelings regarding conflictual aspects of their sexual and emotional contracts. The marriage contract approach (7) uncovered many hitherto unconscious conflicting contractual terms. The source of the difficulty was found to reside largely within the man's intrapsychic dynamics (remote causes), which caused him to precipitate transactions with his wife (immediate causes) that were terribly destructive. She played the game with him. He had to see her as he had seen his threatening seductive mother. He feared being drawn into emotional closeness with his wife and reacted to this anxiety by manifesting hostile depression and withdrawal. The woman reacted in a way that was consistent with her vulnerability and reinforced his fears. Without major changes in their basic adaptations, the prognosis for their marriage was poor. Individual therapy for the man was recommended as the first step in an attempt to interrupt their circular negative interactions. Marital therapy had been helpful diagnostically but left us at a therapeutic impasse.

The husband sent me a note recently thanking me for the referral. He liked his therapist. He said things were quiet and he and his wife were more optimistic. Outcome awaits further developments.

Although sex was mechanically good for this couple, it was affectively inadequate and dissatisfying. This is a syndrome we are seeing with increasing frequency. Inappropriate feelings (or lack of feelings) during or after sex may be due to immediate causes within the couple's relationship (as they were for the wife) or to remote and intrapsychic determinants (as they were for the husband).

CONCLUSIONS

The sexual components of a couple's relationship cannot be separated from their total relationship, either in the reality of their daily life or in treatment. Sex therapy has had and will continue to have a profound effect on marital therapy. The effectiveness of the new sex therapy has substantiated the value of the systems approach and of a multifaceted, goal-directed, task-oriented form of marital therapy. This approach involves the fullest range of the therapist's skills in dealing with those factors that interfere with the patients' collaboration in their own change. Symptom removal and tasks mobilize resistance; an eclectic approach to treatment allows us to make use of a panoply of new and old treatment methods and techniques to deal with these deterrents to change.

Profiles of Couples Seeking Sex Therapy and Marital Therapy

BY ELLEN FRANK, M.A., CAROL ANDERSON, M.S.W., AND DAVID J. KUPFER, M.D.

Assessment of 29 couples seeking marital therapy and 25 seeking sexual therapy at the same institution permitted the delineation of two distinct profiles. Although the two groups were similar in the degree of their sexual and marital difficulties and in demographic characteristics, the relationships of the sex therapy couples were generally characterized by satisfaction and affection, whereas those of the marital therapy couples were often antagonistic. In addition, the sex therapy couples tended to be less conservative and more thoughtful in their approach to life and their problems.

FOR MANY YEARS marital therapy was the sole province of social workers or marital counselors, who concentrated on the overt interactional difficulties being experienced by the couple. The marriage itself was the focus of the therapy, and the sexual aspects of the relationship were rarely, if ever, discussed. However, the recent explosion of scientific knowledge about human sexual experience, coinciding with the women's movement and the new freedom granted women to acknowledge their own sexuality, has focused considerable attention on this aspect of human interaction (1, 2).

At present there are thousands of clinics and individual therapists throughout the country offering what is commonly called "sex therapy." Symptoms of sexual dysfunction that were once considered manifestations of deep-seated psychological problems amenable only to long-term individual psychotherapy are now considered not only eminently treatable, but treatable almost exclusively within the context of short-term intervention involving both members of the affected couple (3). Perhaps because of their divergent origins, marital therapy and sexual dysfunction therapy continue to be thought of as different forms of treatment that attack quite different problems. Yet often the two seem to be inseparable aspects of a complex interplay of action and reaction.

The Western Psychiatric Institute and Clinic at the University of Pittsburgh, which provides both marital therapy and sexual dysfunction therapy in separate specialty clinics, offers a unique opportunity to study couples coming for one form of treatment or the other. This report is a preliminary attempt to examine the similarities and the differences between those who seek marital therapy and those who seek treatment for sexual dysfunction.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with the Department of Psychiatry and the Western Psychiatric Institute and Clinic, University of Pittsburgh School of Medicine, 3811 O'Hara St., Pittsburgh, Pa. 15261, where Ms. Frank is Research Assistant in Psychiatry, Ms. Anderson is Associate Professor of Clinical Psychiatry and Director, Family Therapy Clinic, and Dr. Kupfer is Professor of Psychiatry and Director of Research.

METHOD

In order to study the characteristics of the couples coming for these two modes of therapy, we examined the initial marital evaluation form (KDS-15) given to all couples seeking marital therapy in the Family Therapy Unit and to all couples seeking treatment for sexual dysfunction in the Sexual Behavior Center over a 6-month period. Couples were given the questionnaires at their first appointment and instructed to complete them without consulting one another and return them at their next appointment. KDS-15 is an extensive self-report questionnaire that covers many aspects of a marriage, including individual development and parental family situation, psychosocial history, courtship, current marital relationship, current living situation, premarital and marital sexual activity, the impact of children on the marriage, work and social activities, the use of leisure time, medical history, and attitudes about role behavior in the marriage.

The entire sample of 108 patients was divided by

type of therapy, and overall differences between the two groups were examined. Data on men and women, divided by the type of therapy they were receiving, were also examined. Nonparametric techniques (chi-square tests) were used in this investigation.

RESULTS

Both groups were demographically quite similar, with the modal patient being 31½ years old, married for 7 years, either Catholic or Protestant, white, with a college degree, and 3.4 children. Although an analysis of the husband's type of employment and salary revealed no significant differences between the two groups, it was noted that a larger percentage of wives in the sexual therapy group were working (60% versus 32%, difference not significant).

An analysis of the data on the 29 couples seeking marital therapy and the 25 couples seeking sex therapy revealed that the overall frequency of sexual difficulties was quite similar in the two groups (see table 1). Many of the women who were seeking marital therapy were bothered by inability to reach orgasm, as well as difficulty getting excited and difficulty maintaining excitement. Nearly two-thirds of these women were unable to relax prior to intercourse, and almost half were generally disinterested in sexual activity. Women who were seeking sex therapy had a somewhat higher frequency of individual sexual difficulties than the women in the marital group, although none of the differences reached statistical significance.

The husbands of the women who were seeking marital therapy also tended to be bothered by sexual disinterest. Some men reported difficulty getting and/or maintaining an erection, and more than one-third reported premature ejaculation. The inability to relax and differing sexual habits or practices also constituted problems for a considerable number of these men. Although the men who were seeking sex therapy had more problems with premature ejaculation and were generally less disinterested in sex, there were no significant differences between the two groups.

Just as the couples seeking marital therapy were beset with numerous sexual difficulties, the couples seeking sex therapy seemed to be experiencing considerable marital discord. Outstanding among the interpersonal difficulties experienced by the sex therapy couples were decreased interest in talking to one another, feeling that their spouse did not understand them, frequent arguments, and feeling that their spouse did not fill their emotional needs (see table 2). Most of these couples reported that they were experiencing difficulty discussing problems.

A comparison of the marital complaints of the two groups indicated that marital therapy patients more often complained that their spouse did not understand them, complained about frequent arguments, financial disagreements, and the division of responsibilities within the marriage. A larger proportion of these couples were concerned about their different social needs or desires (see table 2).

More of the sex therapy patients felt that their marriage had exceeded their expectations for compatibility and independence, while more of the marital therapy patients found that their marriage had failed to meet their expectations for social contact (see table 3). Over half of the sex therapy couples rated their marriage as "happy" or "very happy," compared with only about one-fourth of the couples in marital therapy. Not unexpectedly, most of the couples in sex therapy rated their sex life as less satisfying than the rest of their marriage; however, in spite of the high frequency of sexual difficulties among the marital therapy couples, over

TABLE 1
Frequency of Sexual Difficulties in Couples Presenting for Sex Therapy and Marital Therapy, in Percents

Sexual Difficulty	Sex Therapy	Marital Therapy
Women		
Difficulty in reaching orgasm	75	58
Inability to have an orgasm	76	57
Reaching orgasm too quickly	0	10
Difficulty getting excited	80	57
Difficulty maintaining excitement	71	52
Inability to relax	72	63
Disinterest	68	46
Men		
Difficulty getting an erection	13	19
Difficulty maintaining an erection	36	27
Ejaculating too quickly	60	38
Difficulty in ejaculating	8	17
Inability to relax	25	28
Different sexual habits or practices	16	31
Disinterest	24	34

TABLE 2
Interpersonal Difficulties of Couples Presenting for Sex Therapy and Marital Therapy, in Percents

Difficulty	Sex Therapy	Marital Therapy	Significance
Less interested in talking to each other	22	28	n.s.
Difficulty discussing problems	52	69	n.s.
Spouse does not understand them	24	45	$p < .05$
Spouse does not fill emotional needs	46	50	n.s.
Frequent arguments	30	62	$p < .001$
Sexual dissatisfaction	80	60	$p < .05$
Infidelity	8	9	n.s.
Boredom	16	22	n.s.
Too little time spent together	30	28	n.s.
Financial disagreements	12	38	$p < .01$
Disagreement about division of responsibilities	14	38	$p < .01$
Different social needs or desires	16	35	$p < .05$

TABLE 3
Differences Between Couples Presenting for Sex Therapy and Marital Therapy, in Percents

Item	Sex Therapy	Marital Therapy	Significance
Satisfaction			
Marriage is "happy" or "very happy"	56	26	$p < .01$
Sex life is more satisfying than rest of marriage	2	26	$p < .01$
Sex life is less satisfying than rest of marriage	70	33	$p < .001$
Expectations			
Marriage has exceeded expectations for compatibility	20	4	$p < .01$
Marriage has failed to meet expectations for social contact	26	51	$p < .05$
Marriage has exceeded expectations for independence	33	7	$p < .01$
Marriage has exceeded expectations for fun	26	6	$p < .05$
Marriage has exceeded expectations for arguments	42	67	$p < .05$
Patterns of disagreement			
Threaten violence	0	18	$p < .01$
Fight	18	42	$p < .05$
Threaten to leave	11	42	$p < .01$
Talk it over calmly	72	46	$p < .01$
Leave briefly	17	42	$p < .05$
Leave for a day or more	3	22	$p < .05$

one-fourth of them rated their sex life as more satisfying than the rest of their marriage.

DISCUSSION

Our preliminary results lead us to a number of tentative conclusions. It is clear that the two groups did not separate in what would have been the expected fashion, with marital therapy couples experiencing a significantly higher frequency of marital complaints and sex therapy couples experiencing many more sexual complaints. However, questions concerning 1) their expectations about the marriage, 2) specific complaints about the marriage, 3) how they handled disagreements, and 4) various ratings of their overall satisfaction with their sex life and marriage did provide sufficient data to delineate differences between the two groups. Since our goal was to develop a profile of the couples that seek each of these forms of treatment, a closer scrutiny of the results in these four areas may best establish profiles of "personality style" within the relationships being studied.

Although the two groups appeared to be very similar in terms of their demographic characteristics, the personality profile derived suggests major differences between them. The couples were the same age, came from the same ethnic and religious backgrounds, and had approximately the same education. Yet an analysis of the problems they were experiencing, their modes of disagreement, their expectations about marriage, and the extent to which those expectations had been fulfilled indicates two groups that separate along what look like social-class lines.

While the sex therapy couples projected the image of the cerebral, upper-middle-class intellectual, the marital therapy couples projected a blue-collar "Archie Bunker" image. The sex therapy couples seemed to be more comfortable with one another, less conservative in their outlook, and more thoughtful in their approach to their life and their problems. In general, the sex therapy patients were happy with their spouse and involved in basically affectionate relationships, whereas the relationships of the marital therapy couples were characterized by antagonism. Perhaps this dichotomy can be characterized as one between couples who are able to disagree in socially acceptable ways and couples who are not. While the sex therapy couples allowed each other a good deal of independence and privacy, the marital therapy couples seem to be involved in more dependent relationships and did not or could not allow one another privacy. It also appears that a dichotomy existed between couples who had enough money to meet their needs (sex therapy) and couples who did not (marital therapy).

At first we thought that these differences, which seem to be blatantly class-related, could perhaps be explained on the basis of occupation, since neither the husband's earnings nor the level of education had provided significant differences between the two groups. However, the two groups contained similar numbers of professionals and academics at one end of the scale, as well as blue-collar workers at the other end. It may be that personality variables account for the differences, with the preliminary evidence suggesting that the sex therapy patients were clearly less impulsive and more mature than the marital therapy patients. While the latter threatened violence, threatened to leave, or actually left when they and their spouse disagreed, the sex therapy patients tried to talk things over calmly.

Sexual dysfunction therapy at the Western Psychiatric Institute and Clinic is conducted on a slightly modified version of the Masters and Johnson model, requiring two therapists working in conference with both the couple and one another, as well as comprehensive physical examinations and extensive laboratory studies. Marital therapy may involve any of a number of different approaches depending upon the needs of the particular couple, but it rarely requires more than one therapist. Marital therapy lasts an average of 8 weeks and sex therapy an average of 10 weeks. There is a vast difference in the cost of the two types of treatment; sex therapy costs an average of $1,000, compared to about $160 for marital therapy.

This difference may provide interesting leads about the nature of the relationships between the partners in the two groups. Sex therapy represents a considerable investment that can only be interpreted as evidence of the couples' high degree of commitment to their mar-

riage. Thus the decision to come for sex therapy most probably represents a joint decision rather than a unilateral one. In contrast to the marital therapy couples, who had a relatively negative view of their relationship by the time they presented for treatment, the sex therapy couples may have sensed that they had "something worth saving," an idea supported by the fact that they rated their marriages in general as happy. Thus it is not necessarily inconsistent that a number of the marital therapy couples rated their sex life as more satisfying than the rest of their marriage, since this may be a reflection of how bad the remaining aspects of the marriage were.

This study represents the first step in an attempt to assess who should receive marital therapy and who should receive sex therapy. The study asks simply, "Who comes to each type of therapy?" and, in spite of many similarities in the types of complaints the couples were experiencing, it manages to delineate two distinct couple profiles. The next step, of course, is to evaluate treatment outcome in each of the two groups. Only then can we begin to make judgments about whether these couples came to the right clinic for treatment or whether another form of treatment might have been more appropriate.

The present study does, however, have clear-cut implications for the training of both marital and sexual dysfunction therapists. It is obvious from our results that any therapist who is assessing a couple with marital difficulties, but is unable or unwilling to confront the issue of sexual compatibilities, may be performing only half the required task. Equally obvious is the fact that any therapist in sexual counseling must have more than a minimal ability to deal with interpersonal conflicts within the marriage.

Sex Therapy and Psychophysiological Research

RAUL C. SCHIAVI, M.D.

The author discusses two areas of psychophysiological research that may be relevant to the diagnosis and treatment of sexual dysfunction: investigations of sexual arousal in men and studies of nocturnal penile tumescence. There has been no convincing evidence to date of a predictable, generalizable autonomic response pattern to sexual arousal, but neuroendocrine research in this area has shown promise. A close temporal relationship has been found between REM sleep and penile tumescence in normal men–deviations from this pattern may be related to sexual dysfunction. The author suggests that further research is necessary in these areas of potential diagnostic and prognostic significance.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Schiavi is Associate Professor of Psychiatry, Mount Sinai School of Medicine, 11 East 100th St., New York, N.Y. 10029.

UNTIL FAIRLY RECENTLY, our lack of information on human sexual functioning was abysmal. Long after the results of the monumental work of Kinsey and associates on the epidemiology and social aspects of human sexual behavior had been reported, biological research in the United States on human sexual functioning was extremely limited. Masters and Johnson's pioneering investigations have contributed substantially to the current trend of considering human sexual behavior a proper area of biomedical research. This attitudinal change has been illustrated by the increasing number of publications on the biological aspects of human sexuality during the past 10 years in medical and behavioral science journals. There have been more articles published on the biology of human sexual function since 1966 than in all previous years combined.

Recent methodological advances in the measurement of male and female sexual responses have paralleled the establishment of sex therapy programs in institutional settings. Current investigations of psychophysiological aspects of human sexual arousal and

behavior have implications for the understanding of human sexual dysfunctions. Masters and Johnson (1) noted that their philosophy of rapid treatment for sexual dysfunctions evolved from the integration of knowledge on sexual physiology with methods designed to enhance communication between the couple. They have emphasized the need for thorough anatomical, physiological, and metabolic information on sexual function as a basis for the treatment of sexual disorders.

Masters and Johnson's physiological investigations have focused primarily on the correlates of sexual response at the peripheral organ level, with relatively little emphasis on its neural regulation. Their work has provided considerable information on changes in external and internal reproductive organs as well as extragenital physiological responses during the sexual response cycle. They also obtained data on cardiorespiratory reactions such as hyperventilation, tachycardia, and elevation in diastolic and systolic blood pressure during sexual activity. However, sexual arousal and sexual activity may be distinct conditions; there is currently no evidence to substantiate the assumption that the autonomic changes occurring during the early stages of sexual arousal differ only in intensity from the responses associated with overt sexual behavior. We know relatively little about the autonomic and neuroendocrine patterns associated with sexual arousal. Psychophysiological studies of sexual arousal may contribute to our understanding not only of sexual dysfunctions but also of low sexual drive in the face of unimpaired sexual performance.

In this paper, I will briefly discuss two areas of psychophysiological research that are of potential relevance to the diagnosis and treatment of sexual disorders. These areas are 1) the investigation of sexual arousal in men, and 2) studies of nocturnal penile tumescence.

RESEARCH ON SEXUAL AROUSAL

Assessment of sexual arousal is usually based on behavior and verbal reports. However, physiological changes associated with arousal may occur in the absence of conscious recognition. Physiological measures provide the advantages of objectivity, continuous monitoring, and quantitative evaluation. Unfortunately, a review of the studies using various measurements commonly employed in psychophysiological research (electrodermal measures, heart rate, blood pressure, respiration variables, temperature changes, and pupillary responses) revealed that most of these variables are not very sensitive measures of mild to moderate sexual arousal (2). Although there are marked increases in heart and breathing rate during coitus, these measurements do not seem to be sensitive indicators of mild arousal in the absence of sexual activity. Of all the cardiovascular measures evaluated, blood pressure is the only one that has shown a graded response relative to the intensity of sexual stimulation.

In this type of research, it is important to establish that the physiological reactions measured are specific to sexual arousal and do not reflect a response to novelty or to emotions evoked by the experimental situation. Several investigators (3, 4), using concurrent measurement of two or more physiological variables, have attempted to identify a characteristic pattern of autonomic responses that would distinguish sexual arousal from other emotional states such as anxiety or anger. As had previously been the case with other emotions, there has to date been no convincing evidence of a predictable autonomic response pattern to sexual excitation without significant individual differences.

Neuroendocrine Studies

Are neuroendocrine changes more specific and reliable indicators of sexual arousal? Levels of gonadal hormones are promising variables in the assessment of sexual arousal and function. There are data suggesting that testosterone levels may distinguish between two types of psychogenic impotence that have different developmental and behavioral characteristics (5). The significance of this finding is uncertain, however, because of our limited knowledge of the relationship between endocrine levels of testosterone and sexual arousal and behavior in men. This interrelationship has been the focus of considerable attention for many years, but only recently has the development of sensitive methods of hormonal determination made it possible to begin systematically studying relationships between psychological function and gonadal hormones. The interaction could be manifested in two ways: endogenous variations in circulating androgens may influence sexual arousal and activity and, in turn, sexual behavior may modify gonadal secretion. Clear evidence has been found in several laboratories (6–8), including our own (9), of marked minute-to-minute fluctuations of plasma testosterone superimposed on diurnal variations, with maximum levels usually occurring during the early morning. In addition, recent findings (10) suggest the existence of cyclic plasma testosterone variations, with periods ranging from 8 to 30 days. At present, there is no evidence of a correlation between endogenous fluctuations of plasma testosterone and sexual behavior in humans. There is evidence, however, that sexual arousal and activity can increase the circulating levels of testosterone (11, 12), although other researchers have not found this to be the case (13). Because chronic psychological stress has been found to inhibit testosterone secretion in men (14), it is important to take this factor into account in any experimental procedure designed to elucidate the relationship between sexual arousal and testosterone levels.

Penile Erection and Arousal

Increasing attention is being paid to the measurement of penile erection as an indicator of sexual arous-

al. Masters and Johnson indicated that penile tumescence is an early physiological response to sexual arousal in the male that sometimes precedes subjective recognition of arousal. Several devices have been developed to monitor changes in penile tumescence for experimental or diagnostic and therapeutic purposes (15, 16). One reliable method uses a thin elastic silicone tube filled with mercury and sealed at both ends to form a loop. This loop is placed around the shaft of the penis; changes in tumescence produce variations in electrical resistance, which are measured as the tube stretches during erection. Using this method, Bancroft and Mathews (17) investigated the relationship between penile erection and peripheral indicators of autonomic arousal. Erectile, electrodermal, and cardiovascular responses of normal males to sexual and neutral stimuli were recorded in a standardized procedure. Penile erections discriminated between sexual and neutral stimuli, whereas the other physiological parameters, including skin conductance, heart rate, and forearm blood flow, failed to do so. In addition, the correlation between erection and peripheral autonomic measures varied between individuals. Some subjects showed positive correlations between penile tumescence and at least one of the autonomic responses, while other subjects demonstrated no correlation or significant negative correlations.

While we await replication of these findings, it is tempting to speculate with Bancroft and Mathews (17) that erection and autonomic arousal, although usually associated, are independent responses. These two measures may or may not vary together depending upon the subject's appraisal of the sexual and nonsexual components of the situation. The possibility that individuals show specific patterns of autonomic response to sexual stimulation should also be considered. There may be characteristic differences across subjects, with some consistently showing a direct relationship between increased autonomic arousal and penile erection and others demonstrating an inverse relationship.

The existence of response specificity and particularly of a negative association between erection and autonomic arousal may provide a basis for the differential effect of an arousal state such as anxiety on an individual's sexual performance. (Fear of sexual performance is an important immediate causal determinant of erectile dysfunction in some men [1].) An individual who demonstrates a negative relationship between penile erection and autonomic activation may require an optimal low level of arousal for the development of tumescence. This individual may have an idiosyncratic vulnerability to react with erectile dysfunction in the presence of fear or anxiety.

In view of the relevance of these hypotheses to an understanding of the psychophysiology of impotence and the processes involved in the resolution of the dysfunction, it is of interest that there are, to my knowledge, no studies of men with erectile dysfunctions that have assessed the pattern of autonomic arousal and penile tumescence in response to erotic stimulation. This lack of information contrasts with the number of psychophysiological studies that used measures of penile erection to assess sexual preference in male homosexuals (18) and to monitor changes in sexual drive and orientation during their treatment (19).

STUDIES OF NOCTURNAL PENILE TUMESCENCE

Another approach to the study of psychophysiological processes related to sexual function and dysfunction is consideration of the physiological changes in genital structures and gonadal hormones during sleep. Fisher and associates (20) and Karacan and associates (21) were among the first investigators to systematically study the association between nocturnal penile tumescence and REM or dreaming sleep in normal men. They found that episodes of erection began and ended in close temporal relationship to the onset and completion of REM sleep.

The degree and frequency of erection are at their height in early adolescence, when an average of 5 to 7 episodes of tumescence occur during the night and an average of 32% of total sleep time is spent in erection. Although there is a progressive decline in frequency of nocturnal erections from adolescence to old age, the proportion of erection time in relation to total sleep time remains relatively constant between the ages of 20 and 69, ranging from 20% to 30%. Although there is a close temporal correlation between REM sleep and penile erection, this is by no means absolute. Furthermore, there is evidence that each process may be controlled by independent mechanisms that usually coincide temporally but may be unassociated (22–24). The functional and adaptive value of nocturnal cycles of penile erection remains unclear. It has been suggested that erections may be another aspect of the genital physiological activation associated with REM sleep (20).

Jovanovic (25) has indicated that there are definite parallels between disorders of potency, disturbances in the pattern of nocturnal erection, and sleep disorders. He is the first investigator to study the relationship between impotence and variations in the REM-erection cycle. He found that, compared to normal men of the same age group, men with psychogenic impotence had fewer and less intense erections and demonstrated a lack of temporal synchrony between the erection periods and REM phases, with markedly irregular cycles of tumescence. Jovanovic concluded that nocturnal REM erection objectively mirrors the state of a man's sexuality and may be useful in the differential diagnosis of sexual disorders. In view of the universality and regularity of the phenomenon of nocturnal penile tumescence, it is remarkable that there is so little information available on the patterns of nocturnal erection in men with either psychogenic or organic impotence.

In a recent paper on variations of nocturnal penile tumescence as a function of age, Karacan and asso-

ciates (26) summarized their findings on the relationship between nocturnal REM erections and sexual impotence. Based on their evaluation of 55 men with impotence of various etiologies, they concluded that the determination of nocturnal penile tumescence discriminates between organic and psychogenic impotence.

Nocturnal Penile Tumescence and Hormonal Levels

In collaboration with Dr. Charles Fisher, we have initiated in the human sexuality program at Mount Sinai School of Medicine a systematic investigation of patterns of penile tumescence and fluctuations in plasma luteinizing hormone (LH) and testosterone during nocturnal sleep in normal men and men suffering from psychogenic and organic impotence. The first stage of this program has involved gathering normative data on stages of sleep and penile tumescence in relation to levels of LH and testosterone in heterosexual men free from sexual dysfunctions. Frequent serial blood sampling during nocturnal sleep revealed abrupt fluctuations in both hormones, with no significant relationship to REM sleep. There was, however, a consistent tendency for mean testosterone levels to be higher during REM sleep with tumescence than during REM sleep without tumescence. The possibility of an interaction between REM sleep and penile tumescence relative to testosterone secretion deserves further consideration. It has been suggested (27) that changes in testicular blood flow as a result of sympathetic nervous system stimulation may be a determinant of short-term changes in plasma testosterone levels. It may be that the autonomic nervous system activation during REM-associated erections results in rapid increases in testosterone release. Further studies using frequent sampling in a greater number of subjects are needed to clarify the significance of nocturnal penile tumescence in relation to fluctuations in plasma testosterone.

CONCLUSIONS

Sleep studies offer a valuable approach to the investigation of hormonal secretion in terms of central nervous system activity. Concurrent assessment of gonadal hormonal levels and penile tumescence during sleep may provide a basis for needed psychophysiological research in sexual dysfunctions such as impotence. There have been few psychophysiological and endocrine studies of erectile disorders, and no sequential investigation of pituitary-gonadal activity in these patients has yet been reported. In addition to increasing our overall knowledge of the subject, the assessment of endocrine and erectile changes in men with psychogenic and organic impotence may have diagnostic as well as prognostic significance. Penile recording techniques may provide a means to differentiate patients who have similar symptoms but may have distinct etiological or developmental characteristics and may be differentially responsive to treatment. Karacan and associates' observations (26), as well as our own (28), seem to support this possibility.

APA Grant Program for Minority-Group Medical Students and Residents

A small number of qualified minority applicants (including but not limited to American Indians, Asian Americans, black Americans, and Spanish-speaking Americans) will receive residency stipends, assistance in selecting a residency program, expenses to a yearly meeting with other minority fellows to share experiences and administrative help through APA's Office of Minority Affairs. The program is sponsored by APA, with funds provided by the National Institute of Mental Health.

Applications are being accepted now for residencies beginning in July 1976 and subsequent years. Applicants must be U.S. citizens and must have graduated from a U.S. medical school or possess the ECFMG certificate.

For further information write Jeanne Spurlock, M.D., Office of Minority Affairs, American Psychiatric Association, 1700 18th Street, N.W., Washington, D.C. 20009, or call (202) 232-7878.

Relationship Between Dosage and Response to Lithium Prophylaxis in Recurrent Depression

BY ROBERT F. PRIEN, PH.D., AND EUGENE M. CAFFEY, JR., M.D.

The authors analyzed the results of a multihospital collaborative study on the effectiveness of lithium prophylaxis in recurrent depression in terms of dosage and found that serum lithium levels between 0.5 and 0.7 mEq/liter and doses below 1000 mg/day were relatively ineffective in preventing recurrences. Serum lithium levels between 0.8 and 1.0 mEq/liter and doses above 1000 mg/day were associated with a relatively low failure rate. The authors discuss the relevance of these findings to current prescription guidelines for lithium carbonate.

THE MULTIHOSPITAL COOPERATIVE study on lithium carbonate therapy sponsored by the Veterans Administration and the National Institute of Mental Health between 1968 and 1972 (1, 2) helped establish lithium as an effective prophylactic treatment in recurrent depression; lithium was shown to be effective in preventing both depressive and manic episodes in unipolar and bipolar illness. The study also demonstrated that lithium is not a panacea: almost half of the lithium-treated patients relapsed over a two-year period. Attempts to relate treatment outcome to background variables such as age and psychiatric history were unsuccessful (3). However, subsequent analyses revealed that lithium dosage was significantly related to treatment outcome.

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

When this work was done Dr. Prien was Assistant Chief, Central Neuropsychiatric Research Laboratory, Veterans Administration Hospital, Perry Point, Md.; he is now Research Psychologist, Psychopharmacology Research Branch, National Institute of Mental Health, 5600 Fishers Lane, Rockville, Md., 20852. Dr. Caffey is Deputy Assistant Chief Medical Director for Professional Services and Clinical Support Services, Department of Medicine and Surgery, Veterans Administration, Washington, D.C.

DOSAGE GUIDELINES

There appear to be no consistent guidelines regarding prophylactic lithium dosage. The lithium carbonate package insert (4) recommends serum lithium levels of 0.6–1.2 mEq/liter[1]; these levels are usually achieved with doses of 900–1200 mg/day. Some clinicians recommend more aggressive schedules. Schou (5) contends that full prophylactic effect in most patients is obtained only when serum lithium concentration is maintained at 0.8–1.2 mEq/liter. Other clinicians are more conservative and recommend levels between 0.4 and 0.8 mEq/liter (6–8). The American Medical Association Department of Drugs specifically cautions against maintenance levels exceeding 0.8 mEq/liter (9). A few clinicians argue for even lower levels of 0.3–0.6 mEq/liter (10–11).

It should be pointed out that the aforementioned recommendations are not substantiated by published dosage studies and appear to be based mainly on unsystematic clinical observation. There is, however, one point of agreement. All clinicians recommend that maintenance levels not exceed 1.5 mEq/liter because of the risk of toxicity and consider levels below 0.3 mEq/liter ineffective.

METHOD

The study was conducted at 12 Veterans Administration and 6 public or private hospitals. Patients were admitted to the study following hospitalization for acute depression. A complete description of background characteristics is provided elsewhere (1). Briefly, the sample consisted of 76 women and 46 men. All were

[1]Lithium is readily absorbed from the bloodstream into body fluids. As a result, serum lithium level (measured in milliequivalents of lithium per liter) serves as a reliable indicator of lithium concentration throughout the body, and is used to monitor dosage.

under 60 years of age and had experienced at least one affective episode requiring hospitalization during the preceding 2 years and two episodes requiring hospitalization during the preceding 5 years. Their diagnoses were manic-depressive psychosis, depressed type, and recurrent endogenous depression.

Following remission of the acute episode, each patient was stabilized on maintenance doses of lithium carbonate or imipramine. Lithium was administered in 250-mg capsules. Serum lithium levels were stabilized between 0.5 and 1.2 mEq/liter. At discharge, patients were randomly assigned to lithium, imipramine, or placebo. Patients assigned to active medication continued at the established maintenance level. Patients assigned to placebo had identical looking capsules substituted for active medication.

The lithium-treated group included 45 patients. Patients returned to the hospital every 4 weeks to be evaluated, obtain medication, and have their serum lithium levels monitored. Serum lithium levels were obtained from blood drawn by venipuncture before the first morning dose (8–12 hours after the previous dose). Serum lithium concentration was determined by emission flame photometry or atomic absorption spectroscopy.

Each patient was to receive his assigned treatment for 2 years. The treatment physician knew what medication the patient was taking, but the clinical raters operated under blind conditions.

Treatment outcome was evaluated primarily in terms of occurrence of affective episodes, defined as depressive or manic attacks requiring hospitalization or supplementary drugs (i.e., psychopharmacological agents other than the patient's assigned treatment). Patients were also evaluated on a variety of instruments including the Global Affective Scale (3) completed by a psychiatrist at each visit; depressive and manic symptoms were rated not present, mild, moderate, or severe.

In examining the relationship between treatment outcome and dosage, we excluded patients who were unable to remain out of the hospital or off supplementary medication for at least 6 consecutive months. This was to ensure that all patients had an adequate period of stabilization on lithium therapy. Six patients were excluded for this reason. We also excluded 7 patients who had no episodes but were unable to complete the study because of intercurrent illness or failure to keep appointments. The remaining 32 patients were classified as either treatment failures (N=12) or treatment successes (N=20). A patient was considered a treatment failure if he had an episode and a treatment success if he had no episode. The median time of treatment failure was the 17th month of the study. Eleven of the treatment failures resulted in hospitalization; the 12th required continuous supplementary medication.

Treatment failures and treatment successes were compared in terms of lithium dosage. The main purpose of this comparison was to determine whether treatment failure could be explained by insufficient dosage. Another goal was to determine whether dosage guidelines could be established for the treatment of recurrent depression. Three sets of doses were compared: 1) doses administered to treatment failures 6 months before their episode were compared with doses administered to treatment successes at the end of the first year; 2) the same comparison was conducted with doses administered 3 months before treatment failure; and 3) randomly selected doses for treatment failures were compared with randomly selected doses for treatment successes. Findings from the three sets of comparisons did not differ significantly; only the results from the first set are presented here.

RESULTS

Treatment successes received a significantly higher lithium dosage than treatment failures (means at 1275 and 979 mg/day; $p<.05$, two-tailed t test). Treatment successes also had higher serum lithium levels (means of 0.80 and 0.63 mEq/liter), although the difference between groups was not statistically significant.

Table 1 shows the proportion of failures and successes associated with various dosage levels. Fifty-three percent of the patients receiving daily doses of 1000 mg or less were failures compared with only 20% of the patients receiving doses exceeding 1000 mg ($p<.05$, Fisher's exact probability test). Similar results were obtained in comparisons of serum lithium levels (table 2). Fifty-five percent of the patients with levels of 0.7 mEq/liter or less were failures compared with only 14% of patients with higher levels ($p<.05$, Fisher's exact probability test). There was no major difference in treatment outcome between patients with levels of 0.8–1.0 mEq/liter and those with levels exceeding 1.0 mEq/liter.

There was a predictable positive relationship between dosage of lithium carbonate and serum lithium level. Patients with serum lithium levels exceeding 0.7 mEq/liter received an average daily dose of 1393 mg, (range, 1000–2250 mg). The average daily dose for patients with levels of 0.7 mEq/liter or less was 972 mg, (range, 750–1500 mg).

The Global Affective Scale showed no major difference in symptoms between failures and successes at

TABLE 1
Treatment Outcome by Dosage

Dosage (mg/day)	Treatment Failures		Treatment Successes	
	N	Percent	N	Percent
750	5	71	2	29
1000	4	40	6	60
1250	2	25	6	75
1500 and more	1	14	6	86

TABLE 2
Treatment Outcome by Serum Lithium Level

Serum Level (mEq/liter)	Treatment Failures		Treatment Successes	
	N	Percent	N	Percent
0.7 or less	10	55	8	45
0.8–1.0	1	11	8	89
Over 1.0	1	20	4	80

the time the analyzed doses were administered: 25% of the failures and 15% of the successes had mild symptoms. Moderate to severe symptoms were not apparent in the majority of treatment failures until the month preceding the episode. Dosage increases at this time obviously proved unsuccessful in keeping the patient out of the hospital.

Side effects were not a major problem, although 4 patients had moderate to severe gastrointestinal reactions early in the study that necessitated a decrease in dosage. A fifth patient experienced moderately severe hand tremors, and a sixth felt weak and lethargic. Three of these patients could not achieve serum lithium levels above 0.6 mEq/liter because of recurring side reactions.

The failure rate for 13 placebo patients who were able to remain episode free for 6 consecutive months was 69%. This rate is not significantly different from the 55% failure rate for lithium-treated patients with blood levels of 0.7 mEq/liter or less.

DISCUSSION

It should be stressed that this was not a dose-response study, i.e., patients were not assigned to various dose levels. The clinician selected what he considered to be the best dosage regimen for each patient. The only requirement was that serum lithium concentration be maintained at 0.5–1.2 mEq/liter.

Serum lithium levels between 0.5 and 0.7 mEq/liter were associated with a relatively high incidence of failure. This supports Schou's contention that levels below 0.8 mEq/liter are often inadequate to ensure full prophylactic effect (5). However, two factors should be considered before one regards these levels as ineffective. First, these levels may be necessary for elderly and debilitated individuals who cannot tolerate higher doses; it has been reported that some elderly patients respond well to levels as low as 0.3–0.4 mEq/liter (12). Second, the study sample represented a very high-risk population. All patients had been hospitalized at least once during the two years preceding the study; 60% had been hospitalized two or more times. It is possible that a less severely ill population would require lower doses.

The results suggest that levels exceeding 1.0 mEq/liter produce no advantage over levels of 0.8–1.0 mEq/liter. The latter levels are usually achieved with doses of 1250–1500 mg/day. As mentioned previously, not all patients can tolerate these levels. If a unipolar patient (i.e., a patient with no history of manic episodes) is unable to tolerate a level of 0.8 mEq/liter, a switch to maintenance doses of imipramine should be considered. Previously reported findings from this study (1) indicate that imipramine, in doses of 75–125 mg/day, is just as effective as lithium with the unipolar patient. Imipramine should be used cautiously with bipolar patients (i.e., patients with a history of mania) because of the risk of manic attacks, and its use in place of lithium is not recommended.

It is interesting to note that most of the study relapses occurred relatively quickly, often before the clinician had an opportunity to adjust dosage. Thus, the clinician who purposely maintains the patient on low levels with the expectation that dosage can be increased at the first sign of the emerging episode may not be providing the patient with adequate protection.

Finally, the three major sources for drug prescription information in the United States differ in the recommended serum lithium levels for long-term control. The lithium carbonate package insert (4) recommends levels of 0.6–1.2 mEq/liter, the American Medical Association Department on Drugs (9) recommends 0.5–0.8 mEq/liter, and the American Society of Hospital Pharmacists (13), levels of 0.5–1.0 mEq/liter. These varying recommendations, coupled with the findings from this study, emphasize the need for well-controlled studies on lithium dosage that use not only serum lithium levels but other promising monitors such as red blood cell lithium concentration (14). Until such studies are conducted, a significant number of patients may receive either ineffectively low or unnecessarily high doses.

Pavor Nocturnus: A Complication of Single Daily Tricyclic or Neuroleptic Dosage

BY ABRAHAM FLEMENBAUM, M.D.

The author tested the hypothesis that a single bedtime dosage schedule of tricyclic or neuroleptic medication produces increased frequency of night terrors by administering a questionnaire to 30 medical patients who were not receiving such medications and 100 psychiatric patients on either multiple- or single-dosage schedules. Psychiatric patients on multiple-dosage schedules reported no more frightening dreams than the medical patients, whereas almost three-fourths of those receiving single bedtime doses had frightening dreams, a significant difference from the medical sample. This preliminary report is presented to call attention to the possible undesirable effects of a single dose schedule.

BECAUSE OF PATIENT noncompliance in taking multiple (divided) doses of tricyclic and/or neuroleptic medication and because of the lengthy half-life of these drugs, several authorities have suggested giving all of the medication in one dose at bedtime. In fact, one of the most frequently prescribed tricyclics has been marketed on the basis of a single daily (evening) dose. The advantages of this method include sedation to facilitate sleep, decreased side effects (which occur mostly while the patient is asleep), and better patient compliance.

In our clinic, this method has been beneficial in a number of cases, with little or no loss of efficacy. (There does, however, tend to be a lower steady state with longer periods of time between doses [1].) One problem has been that a number of patients have complained of terrifying nightmares, some of which have interrupted sleep, with symptoms of physiological activation accompanied by temporary confusion and disorganization. This description is fairly characteristic of night terrors (pavor nocturnus), with the exception of the amnesia frequently seen in those cases (2). Also, in six of our patients the pavor nocturnus disappeared when the dosage schedule was changed from once a day at bedtime to divided doses three or four times daily. These cases led me to test the hypothesis that single bedtime doses of these medications produce an increased frequency of night terrors.

The author is Associate Professor and Research Psychiatrist, Department of Psychiatry, Texas Tech University School of Medicine, P.O. Box 4269, Lubbock, Tex. 79409.

The author wishes to thank the nursing staff of the Department of Family Practice, Texas Tech University School of Medicine; Brenda Matsler, R.N., St. Mary of the Plains Hospital, Lubbock, Tex.; and Joyce Thurne, R.N., Methodist Hospital, Lubbock, Tex., for their cooperation in obtaining data for this study.

METHOD

A simple one-page questionnaire was developed to obtain information on 1) the presence or absence of dreams and 2) whether dreams were accompanied by confusion, disorientation, and signs of physiological arousal.

The subjects were hospitalized psychiatric patients selected at random and given the questionnaire by nurses, who were instructed to give the questionnaire only to patients who were not senile, confused, or undergoing ECT. For control and comparison, the questionnaire was also given to 30 randomly selected medical outpatients at the Department of Family Practice, Texas Tech University School of Medicine, who were not taking any medication with central nervous system action. (Two of these patients were later found to be taking CNS-active medications such as hypnotics, and their responses have not been included in the data analysis.)

Inpatients at two private facilities (St. Mary of the Plains Hospital and Methodist Hospital) that serve as clinical bases for the Department of Psychiatry, Texas

Tech University School of Medicine, were given the same questionnaire at different times. A sample of 100 psychiatric patients was obtained in this manner. I discarded questionnaires of patients who had been in the hospital less than six days and had not reached steady state blood levels of medication and those who were undergoing treatment for alcohol, barbiturate, and/or other drug abuse. (Incidentally, all of the latter patients reported nightmares with physiological activation.) The final sample of psychiatric patients consisted of 76 individuals.

RESULTS

Approximately 50% of the medical patients (N=15) reported dreams of some kind, but only 4 (14.3% reported frightening dreams and only 2 of these 4 reported psychophysiological arousal.

Of the psychiatric patients, 61.8% (N=47) reported dreams of some kind. Although more psychiatric than medical patients reported dreams, this difference was not statistically significant. However, the psychiatric patients did report significantly more *frightening* dreams (N=21, or 28%) than the medical patients ($\chi^2=14.64$, df=1, $p<.001$, Yates' correction applied). This difference is even more marked when we compare only those psychiatric patients who received psychotropic medication (tricyclic antidepressants and/or antipsychotics) in a single daily dose at bedtime to the medical patients ($\chi^2=17.97$, df=1, $p<.001$, for the entire group given single bedtime doses, and $\chi^2=26.9$, df=1, $p<.001$, for those given tricyclics only) (see table 1). There was no significant difference in the frequency of frightening dreams when psychiatric patients given divided doses were compared with medical patients.

This indicates a clear tendency for more patients given single daily bedtime doses to report frightening dreams. Also, although some patients who received their medication in divided doses did report frightening dreams, most of the reports that included confusion and physiological arousal came from patients given single doses at bedtime: 8 of the 11 patients on tricyclic medication at bedtime who reported frightening dreams noted these effects. Furthermore, one of the single-dose patients reported a clear-cut episode of somnambulism for the first time in her life. Somnambulism, like night terrors, is a phenomenon of stage 4 (slow-wave) sleep (3).

To summarize, psychiatric patients receiving multiple doses of medications reported no more frightening dreams than did medical patients. On the other hand, almost three-fourths of the patients receiving single bedtime doses of psychotropic medication had frightening dreams. This suggests that we may be unintentionally inflicting additional miseries on patients who come to us for relief of their own suffering.

DISCUSSION

All psychotropic drugs seem to produce changes on EEG sleep records. Barbiturates and monoamine oxidase inhibitors produce virtually total REM suppression (4). Phenothiazines and butyrophenones tend to synchronize the EEG tracing (5). Given in small doses (e.g., 50 mg of imipramine orally at bedtime), tricyclics in general seem to produce a moderate reduction of REM sleep (6). However, administration of single doses of drugs like diazepam (10 mg) at bedtime seems to decrease stage 4 sleep (7). Stage 4 is the stage during which some of the most terrifying nightmares (pavor nocturnus) occur (2, 3, 8): for this reason, Kahn and associates (7) concluded that diazepam could reduce or abolish nightmares by suppressing stage 4 sleep. This group of investigators had already observed that chlorpromazine did not reduce the number of nightmares—in fact, two of the most severe nightmares occurred while the patients were on chlorpromazine.

The stage 4 nightmare is rare, with an incidence of only 3% to 4% in school children and less in adults. Its etiology is obscure. Although some nightmares are REM (and not stage 3 or 4) anxiety dreams of varying intensity, the most frightening dreams, causing arousal from sleep and a subjective experience of confusion and fear, usually occur during stages 3 and 4, with concomitant physiological arousal (2, 8).

It is interesting that Jus and associates (9) found that chronic schizophrenics receiving medication in a single bedtime dose had a significantly higher per-

TABLE 1
Frequency of Frightening Dreams for 76 Psychiatric Patients, by Type of Medication and Dosage Schedule

Dosage Schedule	Antidepressants		Antipsychotics		Total	
	Number	Percent	Number	Percent	Number	Percent
Single bedtime dose (N=19)						
Frightening dreams	11	78.6	3	60.0	14	73.7
No frightening dreams	3	21.4	2	40.0	5	26.3
Divided doses (N=57)						
Frightening dreams	3	11.5	4	12.9	7	10.5
No frightening dreams	23	88.5	27	87.1	50	89.5

centage of non-REM (stages 3 and 4, or slow-wave) sleep than did those given divided doses. This dosage also increased the mean percentage of REM sleep, whereas the mean percentages of stages 1 and 2 were significantly decreased.

I am not aware of any similar study on tricyclic antidepressants. However, because of the chemical similarity of neuroleptics and tricyclics, I suspect the results would be the same. Also, in studying enuresis, Kales and associates (6) described a slight decrease of REM and an increase of stage 4 with imipramine, changes that rebounded on withdrawal. Not surprisingly, lithium produces a similar significant increase in slow-wave sleep, although it decreases REM sleep (10).

The results I have reported in this preliminary study should be considered tentative, even though the statistical analysis showed marked effects. The hospitalized psychiatric subjects were a cross-section of patients present in private hospitals during four different weeks and were not preselected or followed in double-blind fashion. Most had other drugs prescribed for comfort and medical conditions. These other drugs included medications that affect the central nervous system (e.g., sleeping medications), although most of the patients received flurazepam HCl, which reportedly interferes little with sleep EEG patterns. Some patients received cardiovascular antihypertensives, antibiotics, and other medications. Furthermore, most patients on tricyclic antidepressants had either a tricyclic antidepressant alone or in combination with a neuroleptic (e.g., perphenazine-amitriptyline HCl) or other combinations with small doses of chlorpromazine, thioridazine, etc.

This preliminary report is presented to call attention to the potential ill effects of single-dose antidepressant or neuroleptic medication and to pinpoint this as a potential area of research. It is worthy of note that, as previously mentioned, single bedtime doses may lower the steady state blood levels of the medication. Another fact to remember is that a recent report (11) summarized previous findings supporting the idea that even though the fatal dose is approximately 30 mg/kg, single doses above 200 mg of imipramine or the equivalent come close to levels of toxicity for certain people (5 mg/kg). Reports indicate that heart blocks, convulsions, and death may occur at times in the absence of signs of adverse effects sufficient to prompt dose reduction. The Food and Drug Administration has refused to approve investigational use of imipramine in children in cases where the total daily dose is too close to the apparent danger point of 5 mg/kg. In our experience, it is not rare to find patients who require doses of 200 mg a day or more for the drug to be effective, and the above information clearly indicates potential dangers if this amount is given in a single dose.

I am currently involved in planning a blind prospective study to evaluate the effects of single-dose versus divided-dose schedules in relation to night terrors, but I feel that there is already sufficient reason to consider each case individually and to weigh the possible advantages of single doses against the disadvantages.

Sexual Attitudes of Hospital Personnel: A Model for Continuing Education

BY DAVID J. WITHERSTY, M.D.

The author describes a program developed to help nurses and other health care professionals deal with the problem of sexual acting out by patients who have been hospitalized for a long time. The program involves group behavior rehearsal sessions with role playing. These sessions resulted in specific suggestions for coping with the problem and have been incorporated into the hospital's continuing education program.

THE DEMAND that the postgraduate health professional keep up in his or her area is increasing. The consumer demands it, professional organizations and institutions are beginning to require it, and, with the advent of such innovations as the medical audit and Professional Standards Review Organizations (PSROs), the government has indicated a strong interest in the maintenance of postgraduate standards. Many of the traditional ways of imparting knowledge, such as lectures, discussion groups, and panels, have been supplemented by such devices as closed-circuit videotape programs, programmed learning texts, and self-assessment evaluations. These educational methods all deal primarily with factual knowledge. How does one continue to grow professionally in areas in which factual knowledge is not needed but an opportunity to review, evaluate, and perhaps change attitudinal stances that might be interfering with one's professional functions is needed?

One approach to this difficult problem, which is used in the department of behavioral medicine and psychiatry at the West Virginia University Medical Center, is a type of role playing. In this paper I will present one of the problems that prompted the department to use this approach and discuss some of the advantages and disadvantages we have found in using this method.

THE PROBLEM

The staff of the behavioral medicine and psychiatry department were asked to assist in the presentation of an in-service training program for the nurses on the staff of West Virginia University Hospital. Nurses from several different units had indicated to their supervisors that they felt uncomfortable and inadequate when confronted with sexual acting out, particularly by patients who had been hospitalized for a prolonged period of time. They asked for a program to help them learn to deal with the problem.

To evaluate and better understand the problem, members of the department held several open discussions with the nurses who had requested help. We also sent out questionnaires to all of the nurses to find out if there were any who were concerned about the problem but embarrassed or reluctant to ask for help directly.

Through the open discussions and the answers to the anonymous questionnaires we found that a lack of factual knowledge was not an issue among the nurses, with the exception of questions related to sexual functioning of the paraplegic patient. Most of the participating nurses stated that they had sufficient knowledge of sexual physiology to discuss a problem with a patient but that their discomfort hampered them from doing so.

The nurses stated that they felt more uncomfortable when a patient of the opposite sex confronted them with a sexual problem. They also said they felt less comfortable about taking the initiative in discussing a sexual problem with a patient. However, some nurses stated that they were concerned that a refusal to take the initiative in discussing a patient's sexual frustrations or needs might result in sexual acting out in the form of masturbation or propositioning the nurses.

The nurses were asked, How comfortable would you be approaching and talking with another professional (doctor, nurse, etc.) about a sexual need or problem of a patient? Their answers were contradictory. In open discussion many of the nurses admitted that they would find it difficult to approach another professional about a patient's sexual problem. However, the answers to the anonymous questionnaires indicated a high degree of comfort in approaching and discussing a patient's sexual problem with another professional (according to a scale on which 5=100% comfort, the average response was 4.06).

Thus it appeared that the in-service training program should be geared toward alleviating the feelings of discomfort that interfered with the nurses' ability to impart factual information. With the agreement of the

Dr. Witherstry is Assistant Professor and Director, Inpatient Service, Department of Behavioral Medicine and Psychiatry, West Virginia University Medical Center, Morgantown, W.Va. 26506.

staff nurses we decided to use behavior rehearsal techniques to reach this goal.

BEHAVIOR REHEARSAL

Although there was expressed agreement in favor of role-playing techniques, it was obvious that there was some concern about trying new behaviors in front of a group of fellow professionals. We therefore decided to conduct several demonstrations with groups of between 25 and 40 people in order to alleviate anxiety. The nursing staff and faculty of our department initiated the sessions. Later, the opportunity to practice discussing sexual matters with another professional acting as a patient was offered on a voluntary basis to smaller groups of from 6 to 8 people. This ensured an opportunity for participation.

The demonstrations were well attended, not only by the staff nurses but by medical and nursing students, social workers, nurses' aides, and orderlies. A male psychology intern in our department, who was not well known throughout the rest of the hospital, took the role of a patient who had been hospitalized for many weeks. He was instructed to make verbal sexual advances toward the various female professionals, who were instructed to practice how they might cope with the situation. We pointed out to the participants that there was no one ideal way of dealing with this particular clinical situation, that mistakes and ineffective attempts were expected, and that we hoped everyone could learn from the mistakes. The only other ground rule was that the staff of the department as well as the spectators could interrupt the participants at any time to offer suggestions for dealing with the situation.

RESULTS

Even in the large-group setting, professionals in the group were willing to volunteer to practice new behaviors. Early in these sessions there was a lot of joking and laughing. The fact that humor used to detoxify a high level of anxiety might have the effect of detracting from the learning experience was openly discussed. The group then decided to try to play it straight.

The participants also discussed the fact that humor was used in a similar fashion on the wards to lessen their anxiety concerning the sexual needs of patients. The potential effect of this use of humor on the patients was discussed, and the danger of these behavioral patterns being viewed by the patient as a rejection became obvious.

As the various participants tried role playing (with suggestions and coaching from the sidelines), a common problem repeated itself with some regularity. Early in the encounter the nurse (or social worker, orderly, etc.) who was talking to the "patient" lost control of the situation when the issue of sex was approached. His or her discomfort was apparent, and we observed a variety of techniques for avoiding the issue—ignoring the reference to sex, changing the subject (often to a concrete clinical issue, such as laboratory test results), or actually leaving the patient's bedside. The psychology intern who played the role of the patient said that he would feel embarrassed or guilty if he were treated this way as a patient; the group as a whole concurred.

After a number of these role-playing situations had been observed, the group developed the following outline of suggested behaviors:

1. The professional should be aware of the first hint that a patient wishes to talk about his or her sexual needs and address the issue promptly.

2. The professional should make it clear to the patient that he or she understands that anyone who has been hospitalized for a prolonged period of time would have sexual needs and frustrations. The group emphasized empathy at this particular stage.

3. The relationship between the professional and the patient should be defined by the professional in a very clear, unambiguous manner. For example, the professional could say, "I can certainly understand your needs and frustrations and as a professional I would like to be able to help you, but in no way will I be willing to act on your suggestions." Some members of the group suggested that at this stage of the conversation it might also be appropriate to acknowledge verbal sexual advances as complimentary. However, they suggested that the professional stress the fact that he or she did not intend to act on the patient's suggestions. The major concern of the group was that the professional be firm in his or her approach and yet not put the patient down.

4. Professionals who find it embarrassing to discuss sexual matters with their patients even after practice sessions should admit their embarrassment to the patient and suggest that they would be willing to find another professional who might be willing to talk to him or her.

The large-group demonstrations were well received. The participants indicated that their anxiety about dealing with this particular clinical situation decreased as they learned and practiced new behaviors for dealing with their own discomfort. We decided to continue with behavior rehearsal sessions, using smaller groups, on the various nursing units. These sessions are now being conducted and are well attended; participation has been maximal. Similar learning experiences are now part of the training program for medical students and physician assistants.

DISCUSSION

Behavior rehearsal techniques are certainly not new. Although originally developed by Lazarus in 1966 as a therapeutic tool, the emphasis of this technique on "affective processes that inhibit or prevent the

implementation of effective social behavior" (1, p. 181) makes it ideal as an educational device:

> In addition to its disinhibiting function, behavior rehearsal also provides an opportunity for patient [or professional] to expand his repertoire of responses through modeling and imitation processes (role reversal) and through his own improvisation. (1, pp. 181–182)

Although it has been our experience that patients receive better care after hospital personnel have participated in the continuing education program, which includes behavior rehearsal sessions, the question has been raised as to what effect these sessions have on the personal lives of the staff members who attend them. Two comments are relevant to this issue.

First, the behavior rehearsal sessions are not designed as self-growth or therapy groups for the participants. The goal of the sessions is to evaluate staff attitudes in terms of effectiveness of patient care. Personal attitudes may lead to professional behaviors that interfere with adequate patient care. The sessions afford opportunities to explore and practice more effective behaviors. The quality of patient care improves when health professionals gain control over their emotions.

Second, although the staff's personal growth per se is not the goal of the program, one would expect that the sessions would result in their having less anxiety and better emotional control, thus allowing them to make more rational personal decisions concerning their own value systems.

In a time when the demand for continuing postgraduate health education is great, professionals must continue to be open to any technique that might help them maintain a high level of professional competency, either in the area of facts or in their emotional and attitudinal stances.

Is Dying Being Worked to Death?

BY RONALD JAY COHEN, PH.D.

In recent years there has been a dramatic increase in the number of books and articles on death and dying. The ambivalence of some writers regarding the value of this proliferation of papers led the author to review and evaluate this literature; he found seven overlapping categories of death-related literature that were of both theoretical and practical value. He briefly explores possible reasons for the rise in this subject's popularity.

THE TREND IN THE popularity of death as an area of scientific inquiry could be described as having gone from "warmed-over" to "hot." In an editorial in the *Journal of the American Medical Association* questioning the utility and value of the burgeoning literature on death, Vaisrub noted that "we are now witnessing an extraordinary influx of essays, editorials, even books and specialized journals, on the subject of death and dying" (1, p. 1909). Others have observed that "death is one of the current fads" (2, p. 190) and that "it is incongruous to envisage death as a bandwagon but this is what it seems likely to become" (3, p. 468). A coup de grace is dealt to the would-be writer in this area by those who argue that everything that could possibly be said on the topic has been said already.

> It is much too easy to write about death. There is no need for statistical evidence and for lengthy references. And no one can claim to have more direct information on the subject from high-up. Perhaps because it is so easy to write about dying, so much is written about it without saying anything new. (1, p. 1910)

Dr. Cohen is Senior Psychologist, Department of Psychiatry, New York University—Bellevue Medical Center, Rm. C-410, Bellevue Psychiatric Hospital, 1st Avenue and 30th Street, New York, N.Y. 10016.

EVALUATION OF THE LITERATURE

Rather than indicting en masse the literature in this multifaceted area, it would seem reasonable to independently evaluate the contributions of the various approaches. Broadly speaking, seven overlapping categories can be distinguished. One is concerned with the care and treatment of the patient in extremis. Publications included here range from research reports and case histories (4–10) to "do-it-yourself" primers (11). Closely related is the category in which phenomena associated with death and dying are examined from a developmental/psychopathological perspective. Representative publications in this category deal with the death-related anxiety of various populations (12–18), the distinction between affective fear of and cognitive preoccupation with death (19), and the elucidation of bereavement processes (20–23), with special reference to the question of normal versus pathological grief (24).

Demographic and epidemiological approaches comprise a third category of papers. Amid the seeming plethora of statistical studies included here are many insightful and compelling findings such as those linking psychosocial variables with the occurrence of either death or suicidal attempts (25–30). Another classification includes publications that expound the numerous sociocultural aspects of death and dying (31–34). A fifth category is reserved for the discussion of legal, ethical, and philosophical issues. This literature ranges from the presentation of guidelines for research (35) to debate over current and increasingly complex clinical issues (e.g., "active" versus "passive" euthanasia and "Patients' Bill of Rights").

The sixth category is comprised of theses that are concerned only coincidentally with death-related issues. Descriptions of the testing of hypotheses derived from such notions as achievement motivation (36, 37), locus of control (38), and other formulations (39, 40) would be included here. A final category is reserved for those papers whose primary contribution is to supplement discussion in any of the other six areas by providing stimulating reports amenable to scientific inference. Nonevaluative transcripts of aged individuals' introspections (41) and heuristic experimental findings open to interpretation (42) are representative samples.

DISCUSSION

If the media accurately reflect popular concerns, then the wide appeal of Kübler-Ross's *On Death and Dying* (43), the extensive coverage given the Quinlan case, and the box-office success of sundry films (e.g., *Love and Death* and *Death Wish*) may be taken as evidence that death-related concerns are not confined to professional journals. How is this heightened general interest in death-related phenomena to be explained? Some may argue that it is the threat of world war and the specter of nuclear annihilation that have compelled individuals to intellectually confront the inevitable. Others de-emphasize international concerns to underscore intranational ones such as the recent rise in cancer-related deaths, the alarming increase in street crime, and the unprecedented increment of political bombings and other terrorist activities in this country. Theologians may point to the decline of the Church and the subsequent unrest stemming from ambivalence attendant on the relinquishment of sacred notions such as the belief in an afterlife. Humanists may argue that the growing literature on death is indicative of a rebellion against cold scientific inquiry and a reawakening of awareness that the dying person is, first of all, a person. There is no shortage of explanations, and those which are put forth are likely to vary within and between academic discipline as well as medical specialty.

Allowing for discussion of ethical and legal issues raised by medical advances, Vaisrub's question concerning the reason for the "current preoccupation" (1, p. 1909) is a cogent one. But whatever the reason for the apparent Zeitgeist, scholarly attempts to amplify, quantify, and reify phenomena related to death and dying have generally had the effect of richly enhancing psychological theorizing and complementing extant dynamic and behavioral intervention strategies. Even the lay media's treatment of this topic has been of educational and perhaps cathartic value.

Is dying being worked to death? I think not. It seems unfair to demean the proliferation of death-related literature as a "bandwagon" if this literature is useful in disseminating the raw data with which behavioral theories and life-supportive psychotherapies can be constructed and/or evaluated. The literature sampled in the seven categories conceptualized herein is only minutely representative of the many recent *novel* contributions to man's appreciation of his mortal dilemma. Untimely deaths have been defined as those that are premature, unexpected, and calamitous (44). In an era when the psychiatric community will increasingly be called upon to consult with moribund patients and their families, a call for a moratorium on death-related publishing would indeed be "untimely."

Computerized Tomography in Patients with Tardive Dyskinesia

BY ALAN J. GELENBERG, M.D.

The author reviews the results of computerized tomography performed on eight patients with tardive dyskinesia to determine whether there was permanent structural damage. No significant abnormalities were found. Although it may not be useful in routine work-ups, this new noninvasive technique might be helpful in differential diagnosis, and its increasing sophistication may suggest further research on tardive dyskinesia.

TARDIVE DYSKINESIA is a syndrome of abnormal involuntary movements associated with neuroleptic therapy. Typically, it involves the tongue, mouth, jaws, and face, but it may also include the extremities and trunk (1). While the etiologic role of neuroleptic medication in this disorder continues to be questioned (2, 3), the syndrome is generally attributed to the long-term use of these drugs (1, 4), which is coming under increasing scrutiny (5).

The prolonged and frequently irreversible course of tardive dyskinesia, even after the discontinuance of neuroleptic medication, has suggested that permanent structural damage may underlie the disorder. Neuropathological studies have reported differing results. Phenothiazine administration has been reported to produce neuronal loss in the basal ganglia of rats (6, 7), and one study of human autopsies revealed greater cell degeneration in the substantia nigra of patients with tardive dyskinesia than in controls (8). Other autopsies, however, have found no pathology (9–11).

Autopsies of patients with Huntington's chorea, which resembles tardive dyskinesia (12), reveal degeneration of the caudate nucleus and putamen (13). Similarly, Duvoisin (14) has observed a woman with severe tardive dyskinesia whose pneumoencephalogram revealed ventricular dilatation consistent with caudate atrophy. The atrophy was greater on the side contralateral to her more severe dyskinesia.

Dr. Gelenberg is Co-Chief, Special Studies Clinic, Erich Lindemann Mental Health Center, Instructor in Psychiatry, Harvard Medical School, and Clinical Associate in Psychiatry, Massachusetts General Hospital, Fruit St., Boston, Mass. 02114.

The author wishes to thank Roger Duvoisin, M.D., James A. Schnur, M.D., and Paul F.J. New, M.D., for their suggestions and information, and Marlene Mieske, R.N., and Carolyn Widen, L.P.N., for their assistance with patients.

A new radiological technique, computerized axial tomography (CAT) scan, has provided a noninvasive view of the ventricles and surrounding tissue (15–18), an area formerly visible only via pneumoencephalography. The purpose of this paper is to report on eight patients with tardive dyskinesia who were given CAT scans as part of the clinical work-up.

METHOD

Subjects

Five men and three women with tardive dyskinesia were evaluated. The patients, whose ages ranged from 17 to 56 years, had been exposed to a variety of neuroleptic medications (chlorpromazine, trifluoperazine, perphenazine, fluphenazine, haloperidol, and thiothixene) for periods ranging from 10 months to 16 years. All had psychiatric diagnoses of chronic undifferentiated or paranoid schizophrenia. No patient had a prior history of neurologic disorder, and the only significant family history was the presence of Parkinson's disease in one patient's grandmother.

Diagnosis and ratings were made using the National Institute of Mental Health Abnormal Involuntary Movement Scale (AIMS), which uses a scale of 0–4 to rate facial and oral movements, upper and lower extremity movements, and trunk movements, and also rates global judgments about abnormal movements in terms of overall severity, incapacitation, and patient's awareness.[1] (This instrument will be described in detail in a future publication.)

Global serverity ratings for most patients were mild to moderate (2 to 3 on the 4-point scale). Perioral movements were present in seven patients, upper extremity movements in six, and tongue movements in five; mandibles, lower extremities, trunk, and head were involved less frequently.

Procedure

As part of the clinical diagnostic process, computerized axial tomography was performed using an EMI scanner. Transverse sections were made at a 25-degree angle to Reid's anatomical baseline, with sections at 2.5, 5.0, and 7.5 cm.

[1]Copies of the AIMS may be obtained from the Psychopharmacology Research Branch, National Institute of Mental Health, 5600 Fishers Lane, Rockville, Md. 20852.

RESULTS

Normal scans were reported in seven patients. One patient, a 40-year-old woman diagnosed as having chronic undifferentiated schizophrenia who had been taking phenothiazines for 16 years, showed mild, generalized cortical atrophy, but her lateral ventricles appeared normal and there was no suggestion of caudate atrophy.

DISCUSSION

No caudate atrophy was observed in any of these patients, and the mild, generalized cortical atrophy seen in one patient was not considered clinically significant. These essentially normal scans might be explained in any of several ways.

Limitations of the Technique

Menzer and associates (19) listed Huntington's chorea as a form of dementia diagnosable by CAT scan, but they did not state what degree of atrophy of the caudate nucleus is necessary to be visible on the scan. Paul F.J. New, M.D., of the Massachusetts General Hospital Department of Radiology, has informally estimated that a "moderate" degree of degeneration of the head of the caudate could be seen using the current computer reconstruction in the horizontal plane, but it is impossible at this time to give a more precise quantification. It is therefore not possible to state how small a degree of degeneration in the patients I have described may have escaped detection. A change in computer integration to reconstruct the coronal plane could conceivably result in the detection of degeneration of a lesser degree, and work is currently in progress to test this possibility.

Nature of the Lesion

It is plausible that if there is degeneration in the caudate in tardive dyskinesia, it is of a much finer degree than the gross changes observed in Huntington's chorea and possibly not visible even with a more precise radiological technique. The caudate degeneration Duvoisin (14) observed on pneumoencephalography may have represented an incidental finding or another illness. Alternatively, there may be no morphological lesion underlying the syndrome, but rather a biochemical one, such as neuronal supersensitivity to dopamine (4).

Nature of the Sample

The small number of patients studied raises the question of sampling, but the absence of positive findings in any of these patients suggests that changes that might be found using a larger sample would have a low incidence. The group was heterogeneous, with a wide age range and a large variety of medications. All had dyskinesia that had persisted for at least 4 months, suggesting the truly tardive or persistent form of the disorder, rather than withdrawal dyskinesia (4).

CONCLUSIONS

The technique of computerized tomography is an exciting innovation in the neurosciences. The procedure takes approximately 20 minutes, causes no discomfort to the patient, and provides an in vivo view of structures formerly visible only via the very uncomfortable and potentially hazardous pneumoencephalogram. At the Mayo Clinic, the use of pneumography decreased by 60% after the introduction of the CAT scan (18). On the basis of the data I have presented, the CAT scan in its current program does not seem useful as a part of the routine work-up of patients with tardive dyskinesia. However, it may be valuable when the differential diagnosis of this or other neuropsychiatric syndromes is unclear. The sophistication of the technique is growing, and further investigation into its value in tardive dyskinesia is planned.

Hypothalamic Tumor Presenting as Anorexia Nervosa

BY GEOFFREY B. HERON, M.D., AND DONALD A. JOHNSTON, M.D.

The authors describe a patient with symptoms of anorexia nervosa who was initially treated on a psychiatric ward but was later found to have a hypothalamic tumor. They recommend repeated neurological and endocrine evaluations for patients with anorexia nervosa who are unresponsive or only partially responsive to psychiatric treatment. Initially negative medical evaluations, obvious psychopathology, and even some response to treatment may all prove insufficient to rule out organic disease.

THIS PAPER describes a patient with an appetite disorder initially diagnosed as anorexia nervosa but later ascribed to a pinealoma affecting the hypothalamus. Despite theoretical and experimental evidence relating hypothalamic function to control of appetite (1), few cases have been reported in which hypothalamic dysfunction first presented behaviorally. Our patient illustrated the difficulty of discriminating between emotional and organic pathology early in the evolution of a syndrome. He had behavior abnormalities without endocrine or neurological deficits. Although this patient's tumor, an ectopic pinealoma, is rare, the presenting symptoms parallel some features of anorexia nervosa and may lead to a misdiagnosis.

CASE REPORT

First Admission

Mr. A was a 24-year-old self-employed single man with persistent weight loss unexplained by repeated medical evaluations. A diagnosis of anorexia nervosa had been made when he entered a state psychiatric hospital for treatment. Weight loss continued there for 3 weeks, and he was transferred to a psychiatric ward in a Veterans Administration hospital with a recommendation for hyperalimentation.

Mr. A had anorexia, nausea, and vomiting after an honorable discharge from the Army 2 years before admission. Nausea and vomiting ceased after 5 months, but his weight gradually fell from 132 pounds to 72 pounds at admission; he was 6 feet tall. He had progressively lost interest in previously enjoyed activities and sexuality.

The patient had not dated in high school, but while in the Army had courted a girl for several months. Although he wanted to marry her, the relationship ended when she refused to leave her native country. The broken engagement upset him, but he felt that after 2 years he had "gotten over it."

Mr. A, the second of four boys, was the only child remaining at home with his parents. His father was a mechanic and his mother a housewife. The mother's obesity was the sole instance of family weight disturbance. The parents confirmed that the patient had always been thin but without marked fluctuations in weight, and that he was a "finicky eater." The mother became increasingly distraught during her son's prolonged weight loss and devoted extraordinary attention to feeding him; she regularly cooked separate menus for husband and son, had stocked a large pantry with excessive quantities of food, and cajoled her son to eat more. She seemed personally injured by his continued wasting. The patient's father tried to remain calm and objective, and he rarely expressed his frustration in the patient's presence. He seemed to feel stuck between his son's bewildering illness and his wife's rather overwhelming anxiety about it.

The patient's early development and history were unremarkable. Although he had been myopic since childhood, his vision had not changed recently. He had occasional headaches, but there were no other neurological symptoms. He had not been hyperactive, nor did he use excessive activity to lose weight.

The initial physical examination revealed little except the striking cachexia. Gross testing of visual fields and funduscopic examinations were within normal limits, as were the patient's hair distribution and the size of his testicles. His lack of concern about his illness was striking, but he did not insist that he was overweight or trying to diet, as patients with anorexia nervosa often do. His affect was rather flat, and he seemed somewhat withdrawn and listless, but he did not appear psychotic or display signs of organic impairment. He stated he would rather go home than to another hospital, but agreed to admission.

In the hospital his evaluation continued in consultation with the medical service. His completed work-up included thyroid function tests, plasma cortisol levels,

The authors are with the University of Colorado Medical Center, 4200 East Ninth Ave., Denver, Colo. 80220, where Dr. Heron is a resident in psychiatry and Dr. Johnston is Assistant Professor of Psychiatry.

urine specific gravities, D-xylose excretion, brain scan, skull X rays, total bowel X rays, and a small bowel biopsy. All tests were within normal limits.

After evaluation Mr. A was started on a behavior modification regimen in which his ward privileges and time for socialization were dependent upon a daily weight gain. He reluctantly agreed to this program, but insisted that he had no control over his weight. He began to sabotage the treatment by visiting outside allowed times, sneaking candy while refusing a high calorie diet, and protesting that the food cooked by the hospital was inedible. Even after direct instructions his mother refused to stop bringing home-baked snacks to him.

After repeated adjustments were made in the treatment program to reward the patient for weight gain and to minimize his unusual eating habits, he slowly began to gain weight. He did not recognize any progress, however, and grew increasingly angry at the staff for imposing what he considered unfair treatment. After gaining 15 pounds in 2 months, he signed out against medical advice with his family's approval.

The psychiatric staff concluded that this family could not tolerate interference with their shared psychopathology, in which conflicted feeding was a prominent feature. Although his weight gain had been limited, the patient left the hospital convinced he could do better at home. Follow-up telephone contact 2 months after discharge showed that he felt better and had continued gaining weight; he then weighed 99 pounds.

Second Admission

Five months following discharge Mr. A returned to the hospital as an emergency medical admission. He was semicomatose, dehydrated, had a serum sodium of 180 mEq/liter, and was almost totally blind. Further studies revealed a full-blown syndrome of pituitary and hypothalamic destruction, with diabetes insipidus, decreased thirst sensation, abnormal thermal regulation, decreased adrenal, thyroid, and gonadal hormones, and optic atrophy. A pneumoencephalogram showed a mass lesion in the area of the hypothalamus, and a subsequent biopsy provided the tissue diagnosis of an ectopic pinealoma. Following these diagnostic studies and careful medical management of hormonal replacement, he began a course of radiation therapy, a treatment to which pinealomas have proven sensitive (2).

DISCUSSION

Anorexia nervosa is a psychiatric syndrome characterized by excessive weight loss and malnutrition resulting from reduced caloric intake, which may be due to irrational self-imposed dieting through willful control of appetite or to the experiential loss of appetite. Although the disorder occurs in men, it is most typically seen in adolescent girls ranging in age from prepuberty to young adulthood (3, 4). Its most typical feature is thought to be a dread of obesity, frequently associated with a distorted body image and the patient's insistence on continued weight control or loss in the face of externally obvious wasting (3, 5). The patient's premorbid personality frequently includes constricted compulsive rigidity and schizoid traits (6). Anorexia nervosa patients usually have an ambivalent relationship with one or both parents; often one parent is overly concerned and solicitous and attempts to coerce or inveigle the patient to eat (4).

Anorexia caused by infections, extracranial malignancies, or other conditions may be ruled out by the usual physical work-up. Special diagnostic attention should be given to the possible presence of tumors affecting the pituitary-hypothalamic axis, which are generally manifested by nonspecific neurological symptoms such as headaches and visual field changes, and by endocrine abnormalities. Ectopic pinealomas are usually seen in adolescent or young adult males, and present with a characteristic triad of diabetes insipidus, pituitary dysfunction, and neurological deficits (7). Puschett and Goldberg (8) suggested that the first two components may appear well before any neurological involvement. The diagnostic indicators that are most helpful are skull films, which reveal the calcified pineal, abnormal urine specific gravities, and decreased levels of serum cortisol and gonadal and thyroid hormones. Pneumoencephalography revealing a hypothalamic mass is usually definitive. Electroencephalograms and brain scans do not contribute to diagnosis (8).

Although Mr. A was a man slightly outside the usual expected age range of anorexia nervosa, he otherwise fit many criteria for diagnosis of this syndrome. For 2 years he had maintained a low weight and suffered progressive anorexia, which by the time of admission was profound. His personality pattern included social isolation, rigidity, aloofness, ambivalence, and a nearly symbiotic relationship with his mother. This relationship between mother and son was highlighted by her attitude and behavior about his eating. His extensive physical work-up revealed normal endocrine function, his pineal was not calcified, and his urine specific gravities were within normal limits. It is interesting that only 5 months prior to the development of diabetes insipidus and panhypopituitarism his endocrine studies were normal. We speculate that his 2-year period of anorexia resulted from the insidious growth of the ectopic pinealoma and was the first symptom of this tumor.

This case makes clear several points relevant to anorexia nervosa. Progressive brain pathology may not be revealed in one examination, and a slow response to treatment should prompt reexamination. It should also be kept in mind that obvious individual or family psychopathology may co-exist with and does not rule out a brain lesion. Finally, although psychiatric treatment may alter organically induced failure to eat, successful psychological intervention does not rule out brain pathology.

LETTERS TO THE EDITOR

Auditory Hallucinations

SIR: Hallucinations observed during the early phase of psychotic episodes are usually auditory, even though man uses vision as his principal means of perception after the fourth postnatal month (1). In order to gain some insight into this phenomenon, the development of auditory and visual perceptions in newborn kittens and human infants under various conditions was studied by the best available method—the behavior of the auditory and visual evoked potentials. According to current concepts the P_3-N_4 wave complexes are closely related to intracerebral elaborations such as cognitive processes and decision making (2). The behaviors of auditory and visual evoked potentials of newborn kittens exposed to various recurrent conditions were compared to those of kittens reared under uneventful conditions, and human infants subject to recurrent crying spells of unidentified etiology (absence of detectable pathological changes) were compared to infants whose lives were uneventful.

Randomly delivered pleasant auditory stimuli resulted in earlier maturation (decreased latency, increased amplitude, and changes in wave shape) of auditory evoked potentials in the kittens. Visual deprivation (taped eyes during the first three postnatal weeks) delayed maturation of the visual P_3-N_4 wave complex, with concurrent earlier maturation of the auditory P_3-N_4 wave complex. Recurrent early exposure to stressful experiences (disturbing noise, hunger, cold, etc.) resulted in a minor but statistically significant delay in maturation of the visual P_3-N_4 wave complex and a statistically significant increase in maturation of the auditory P_3-N_4 wave complex.

The human infants with recurrent crying spells had a statistically significant delay in development of visual evoked potentials compared to controls with comparable IQ and attention span.

These observations suggest that the genetically preprogrammed maturation of sensory evoked potentials may be altered through postnatal experiences, resulting in a tendency toward delayed maturation of visual evoked potentials and a prolonged prevalence of hearing as the means for perception of environmental events. Perception through a sensory modality proceeds by registering incoming stimuli through a peripheral sensory receptor, transmitting this signal to central receptors, comparing it with preexisting engrams of the same sensory modality, evaluation, decision making, and (if possible) execution of the decision. This process requires both functioning peripheral and central anatomical systems and a minimum memory bank of engrams of the same sensory modality.

Morphological maturation of the auditory system is faster in mammals. Also, intrauterine life seems to permit accumulation of auditory engrams but not visual ones. The observations on the development of the P_3-N_4 wave complex of auditory and visual evoked potentials suggest that coping with recurrent early postnatal stressful situations consumes time and energy and works at the expense of lack of accumulation of the minimum visual memory bank necessary for efficient use of visual perception. Prolonged use of auditory perception results in reinforcement and in accumulation of auditory engrams containing unusual elements (e.g., pain due to stresses). Therefore, recall by similar painful (anxiety) experiences in future life of reinforced auditory memory traces is facilitated. This is one of the potential sources of auditory hallucinations.

An Expanded Acknowledgment

SIR: I am writing to amplify the acknowledgment given to Ronald S. Poze, M.D., in the footnote to my article, "The Immediate Effects of Chlorpromazine in Newly Admitted Schizophrenic Patients" (October 1975 issue). I feel that my original acknowledgment did not do justice to Dr. Poze's contribution, which consisted of suggesting the idea for the research and participating in the development of the research design.

Still More on the Semantics of Hysteria

SIR: I would like to respond briefly to Dr. Edward Margetts' letter "The Semantics of Hysteria Continued" (January 1976 issue). I understand his concern about the use of the term "Briquet's disorder"; this concern has been expressed for some time by a number of psychiatrists and for various reasons.

As a member of the St. Louis group in which much of the validating research has been done (begun by Drs. Robins and Guze), I can report that the eponym was chosen with the hope of minimizing controversy. The term "hysteria" has never been precise, referring to myriad symptoms and syndromes. Briquet's disorder, on the other hand, *is* precisely defined. If one is familiar with the literature on the subject, there is little question what is meant. Briquet's disorder is

thought by many of us to be the heart of hysteria, the nuclear disturbance, with a set of surrounding phenomena that are more or less related.

As a member of the APA Task Force on Nomenclature and Statistics, I can comment that we have chosen to speak in a generic sense of hysterical disorders. These disorders include a number of fragmentary clinical states, many of which are poorly understood. Briquet's disorder, identified by the eponym and by a lengthy literature, is central.

There was considerable discussion within the task force about what Briquet's disorder should be called. The matter was decided by vote, with Dr. Spitzer, the chairman, voting against adopting the eponym. Dr. Spitzer's view may have failed to carry because no acceptable alternative to "Briquet's disorder" was found. "Polysomatizing disorder" was suggested, but it was rejected because of its confusing implications.

Admittedly, the history of the term "hysteria" is the history of a problem, although the major disorder has been clearly defined. Dr. Margetts suggests that we all know what hysteria means. That may be true. Each of us knows; unfortunately, few of us agree.

ROBERT A. WOODRUFF, JR., M.D.
St. Louis, Mo.

SIR: I happen to agree with the view that all efforts should be made to find a noneponymic term for the category that is now referred to as Briquet's disorder. I believe that "polysomatizing disorder" conveys the essential notion, namely, that Briquet's disorder involves somatizing, the expression of emotional conflict or problems by medically unexplained physical symptoms. Since the essence of the condition is that somatizing involves multiple organ systems, the prefix "poly" is necessary to avoid confusion with other conditions in which somatizing may be involved.

I was unable to convince the other members of the task force of the wisdom of this view. However, at a forthcoming conference to critically evaluate *DSM-III*, we will put the issue to a group of distinguished nosologists for their assessment. Then, who knows?

ROBERT L. SPITZER, M.D.

CAT Scans in Children with Behavior Disorders

SIR: Computerized axial tomography (CAT scan) is a remarkably versatile and accurate new method of examining intracranial contents. The technique is rapid, entirely noninvasive, and can detect a wide variety of lesions, (neoplasm, hemorrhage, edema, cysts, calcifications, and other abnormalities), often with greater sensitivity than either angiography or pneumoencephalography. Moreover the CAT scan affords an opportunity to evaluate the central nervous system (CNS) in individuals who may have brain disease when there is too little likelihood of positive findings to justify diagnostic procedures that entail any risks. Such a situation preyails in children with learning and behavior problems that are often ascribed to underlying brain damage, although the evidence of CNS impairment is mostly presumptive. The high cost of CAT scans prohibits widespread screening of these children, but the method might have some potential in increasing scientific understanding of these disorders.

As a pilot approach, we selected 4 children with the greatest evidence of CNS impairment from a population of 35 children hospitalized for the treatment of severe emotional disorders. There were 3 boys and 1 girl between the ages of 6 and 12 years. Judgments of "organicity" were based on independent psychiatric, psychological, and EEG assessments. Each child had a history compatible with some kind of CNS damage and at times displayed hyperactivity, aggressive outbursts, and/or autistic behavior. They had significant learning disabilities and tended to show large discrepancies between verbal and performance WISC scores and impairment in measures of visuomotor integration. EEGs were markedly or severely abnormal, with both generalized and focal electrical abnormalities. None of the children had positive neurological findings, although "soft signs" such as awkward gait and poor coordination were present. A control group of 4 children was chosen from the same population as having the least likelihood of CNS pathology because of the relative absence of the previously described characteristics. All children were referred for CAT scans; the radiologist did not know which children were presumably brain damaged and which were not (the brain-damaged group, however, received the procedure first). Results of the scan in 3 of these children were interpreted as entirely within normal limits. Before further studies could be accomplished, the fourth child in the brain-damaged group developed an acute myasthenic crisis that established the neurological diagnosis without need for further investigation. At this point, the study was terminated without scanning the children assumed to have no CNS disorder because of the negative results in the other group as well as the expense of the procedure.

This pilot experience suggests that the CAT scan is unlikely to provide additional evidence about a neuropathological basis for severe learning and behavior problems of childhood.

Art Is Not Mad

SIR: The *Journal* is to be commended for using as a lead article an English professor's work, "The Madness of Art" by Leon Edel, D. Litt. (October 1975 issue). We have long known that artists have their own road to the unconscious, and we too often have ignored the contributions they make to our understanding of man. The poets know the sense and beauty of man's unconscious. There is a kinship between us, and it is not our mutual interest in what Dr. Edel calls a "tristimania," Dr. Benjamin Rush's term for agitated depression.

In his tribute to Dr. Rush, Dr. Edel makes herculean but procrustean efforts to wed our field to his; as if that were not strained enough, he gives us the bicentennial squeeze play. Dr. Edel gives a respectable interpretation of Dr. Rush's dream, although it is obviously and naturally retrospective. It is a dream of Dr. Rush's impotence. Fine. Freud would go along with that. It is hard to ignore the symbols of the tri-

dent, steeple, ball, and the inability to control the elements. But Dr. Edel goes too far when he says, "It was a dream of revolutionary America . . . or of a Britannia that claimed to rule the waves. . . . The dream was prophetic in its warning against national megalomania. It said that neither man nor nation alters natural forces." Not only is this a squeeze play, but don't we alter natural forces?

The title of the article is another attempt, perhaps unconscious, to join poetry and psychiatry. In a tribute to Dr. Rush, we are given the dangerous impression that art is mad. It isn't. Dr. Edel knows this and I await with anticipation his further insights about poets and their miraculous awareness of life.

MAX SPITAL, M.D.
White Plains, N.Y.

Dr. Edel Replies

SIR: Dr. Spital's letter seems ambivalent and wanting in precision of phrasing. He uses such words as "herculean" and "procrustean" to characterize a paper that simply assumed that the material of the psyche, whether thrown up as symptom or as poetry, can legitimately concern my humanistic discipline as well as his.

That Dr. Spital did not notice my allusion to Lombroso I can only regard as a bit of "selective inattention." My title for the paper was ironic. I was not suggesting that artists are madmen, as should be obvious to anyone who reads the paper carefully—particularly my synopsis of Henry James's "The Middle Years."

I did not attempt to interpret Dr. Rush's dreams. I treated them as poems or fables, which is the only way a humanist can treat dreams, since he is not an analyst and is without license to deal with such material therapeutically. Dr. Rush's fables spoke to me as a symbol of our inability to change history, even when we plan to assassinate presidents of other countries or bid earthquakes to go away. We bring slight modifications by staging wars, but history has a way of determining its own fateful course in spite of wars. Finally, I do not think I "strained" to bring in the bicentenary in a "squeeze play," as Dr. Spital says. Dr. Rush did after all sign the Declaration of Independence.

LEON EDEL, D.LITT.
Honolulu, Hawaii

Reducing Oral Medication with Depot Fluphenazine

SIR: There are several other explanations for the observations reported in "Fluphenazine with Other Antipsychotic Drugs" by Guy Chouinard, M.D., and Rejean Fontaine, M.D. (letter to the editor, July 1975 issue). Drug monitoring combined with vigorous attempts to reduce all other medications in the past 4 years at the Psychiatric Hospital, Royal Park, Victoria, Australia, has been successful (1). Fluphenazine decanoate has fewer side effects and a longer duration of action than fluphenazine enanthate. This partially explains why 95.7% of the authors' patients who were given the latter drug required an antiparkinsonian drug. A survey in February 1975 of 379 patients in our facility revealed that only 30.3% were on these anticholinergic drugs. Previous surveys had revealed a much higher percentage (e.g., 57.4% in 1973). The almost 30% reduction resulted from a determined attempt to cease all oral medication and from reeducation of hospital staff and standardization of the principles involved in managing these complex depot phenothiazines.

Another sample on injections for a mean of two years (2) indicated that 45.1% were still on antiparkinsonian drugs and 4.3% had not been on these drugs at all. We then looked at the time taken to cease administration of antiparkinsonians. The 49.6% of patients for whom these drugs had been discontinued were assessed for mean duration of time spent on antiparkinsonians: in females it was 20.07 months and in males, 15.83 months. Thus we believe there is a difference between oral and intramuscular phenothiazines in terms of time that antiparkinsonian medication is required. Other contributions to the reduction include increasing the interval between injections and reducing the dosage.

The February 1975 survey showed that 24.9% of the patients received oral medication other than an anticholinergic antiparkinsonian (mainly benzodiazepines and tricyclic antidepressants), but only 8.7% received other phenothiazines. The benzodiazepines have a definite role. Nitrazepam is useful as a hypnotic and diazepam is useful for the side effects such as akathisia.

As well as potentiating the anticholinergic side effects of depot fluphenazine, concurrent oral medications can have nontherapeutic drug interactions and lead to other problems such as drug dependency, insomnia (3), and potentiation or worsening of tardive dyskinesia (4). The physician should attempt to reduce all oral medication as soon as possible.

PETER MARRIOTT, M.A.N.Z.C.P.
Melbourne, Australia

Dr. Chouinard Replies

SIR: The main point is to try to avoid polypharmacy in the treatment of schizophrenic patients. Dr. Marriott is not only reporting that 8.7% of the patients treated with fluphenazine were also receiving other phenothiazines, but that 16.2% were receiving benzodiazepines or tricyclic antidepressants. Tricyclic antidepressants have not been demonstrated to be of therapeutic advantage in combination with neuroleptics (1). As far as benzodiazepines are concerned, double-blind controlled studies have not shown them to help schizophrenic patients. Recently it has been reported that two schizophrenic patients out of six with high levels of anxiety treated with a dose of 150–300 mg/day of chlordiazepoxide were significantly helped (2). Thus Dr. Marriott's suggestion to reduce oral medication with depot fluphenazine does not

seem to apply to his use of benzodiazepines and tricyclic antidepressants, medications for which there is no rationale in the treatment of schizophrenia.

The use of antiparkinsonian drugs in the treatment of drug-induced pseudoparkinsonism is a more complex issue. The difference of incidence in the percentage of patients taking antiparkinsonian drugs could be explained by the doctor's tolerance or nonrecognition of extrapyramidal side effects. It would be interesting to know the percentage of patients presenting bradykinesia or akinesia when treated with fluphenazine alone. Unfortunately, bradykinesia is very often confused with psychomotor retardation in schizophrenic patients and considered as a residual schizophrenic defect (3).

Montreal, Que., Canada

Another Group Heard From

SIR: I read "History and Analysis of a Leaderless Group of Professional Therapists" by Winslow Hunt, M.D., and Amnon Issacharoff, M.D. (November 1975 issue) with interest since I have participated in and reported on a leaderless group (1–3). Our group seemed satisfactory to the participants, and it certainly satisfied me. The report by Drs. Hunt and Issacharoff describes a less satisfactory experience, which leads me to ask the following questions:

1. Was the group too large? Insight groups usually have five to eight members. Many group therapists think that therapy is difficult with more than eight patients.
2. What was the average age of group members? In our group the youngest member was 45.
3. Did the mixture of professionals from different disciplines contribute to fragmentations?

Finally, I hope that Drs. Hunt and Issacharoff will comment on the following point. Our group was recruited and started with a clear understanding that it was a therapy group. Individuals who were not interested in therapy did not come. In this sense our membership was carefully selected. The group described by Drs. Hunt and Issacharoff started for one purpose (supervision) and then tried to change to another (therapy). I suspect this is difficult to do.

In a panel on leaderless groups at the annual meeting of the Los Angeles Group Psychotherapy Society, all the participants were in, or had been in, a leaderless group. The dynamics described in that meeting seemed similar. There were two groups that began as case discussion. Both of them had difficulty when they tried to change to therapy groups, while a group of Jungian analysts that started with a clear understanding that it was a therapy group did not experience such difficulties.

The authors' comments about the midlife crisis and the dynamics of their group seem accurate and very similar to our group.

From our experience I have a strong impression that the leader is not necessary when the group is composed of experienced therapists. In fact, the leader becomes a restrictive solution. I wondered if the authors' group had difficulty because some members wanted to hide behind case presentations or a leader? It takes great courage, good luck, and the right circumstances to even begin to be honest. Our group was relatively successful because members were able to be open, honest, and direct with one another. Do leaders maintain safety by inadequately helping the group to maintain restrictive solutions?

FRANK KLINE, M.D.
Los Angeles, Calif.

Drs. Hunt and Issacharoff Reply

SIR: We appreciate Dr. Kline's thoughtful letter and wish to respond to his questions point by point.

Size did not seem a crucial or limiting factor in our group. When the group engaged in peer supervision or discussion of countertransference issues, it functioned very well despite its relatively large size. If it had become a true insight therapy group, we might have noticed a constraint imposed by size.

Our average age was about 37, making ours more of a midlife group than Dr. Kline's. I would expect that the members of his group had probably, for better or worse, made some peace with those conflicts characteristic of the midlife crisis and gone on to struggle with other issues.

Differences of professional background were irrelevant in our group. Polarization occurred on many issues, but never along that dimension.

Dr. Kline's comment about changing the group purpose in midstream contains an astute observation. In an as yet unpublished paper we have discussed group dynamic issues in more detail, including a long section on the difficulty or impossibility of changing the group contract or goals once the group is already in progress. Dr. Kline's group may have a happier history than ours largely because of a clear initial contract that was not changed.

Dr. Kline's suggestion that a leader is not necessary in a group of experienced therapists requires more extensive comment. In our opinion the fact that the group members were experienced therapists affected the language and content of group interaction but had little effect on the overall history of the group. The relationships between groups and their leaders involve very fundamental and strong group processes against which the psychological sophistication of the members is but a fragile shield. The laws of individual psychology and of group process are binding for all of us. The deeper our knowledge of those principles, the more we

can make use of them, but we are always subject to their force.

I can well imagine groups in which the members avoid self-revelation by hiding behind case presentations or other discussions of subject matter. With our group, it was the other way around (this may not be unusual). We tended to avoid exposing material relative to work competence by diversionary self-revelation.

We believe that it is in the nature of groups to create leaders and that it is in the nature of groups and leaders to be in conflict. The very existence of a group creates security in its members that sets the stage for their regression to a more childlike state. This activates dependency needs that result in a wish for a leader, which causes the group to create a leader. Once a leader is differentiated from the group, his very role makes him separate from the group and in some way antagonistic to it. Every group experiences its leader as restrictive and every leader experiences his group as recalcitrant. Leaders are judged (rightly so) by the nature of the restrictions they place on the group, but every leader must do this to some extent.

Without a leader who can keep his orientation to the group task and maintain the basic culture of the group and the conditions that support its cohesiveness, a group would lose its purposefulness and become a homeostatic structure satisfying the needs of group members. In order to function as a leader, an individual needs some base outside the group itself so that he is not dependent on the group for his sense of self or purpose. In this sense, every group with a task needs a leader or, as we would prefer to say, a leadership function. The leadership function need not be embodied in one individual. It can move from individual to individual, it can be contained in the relationship of the group to some outside institution or society or in some commonly held group ideal. There may be still other ways of embodying the leadership function.

We suspect that Dr. Kline's group contains a leader or leadership function in the sense discussed above. It is probably covert and functioning well, but could be discerned through careful observation of the group process.

WINSLOW HUNT, M.D.

Dignity, Dilemmas, Diagnosis

SIR: I would like to comment on "A Case of Petit-Mal Status: A Diagnostic Dilemma" by Michael Weissberg, M.D. (November 1975 issue). It seems that petit-mal status is not only a diagnostic problem but a problematic diagnosis. As Dr. Weissberg noted, "the independence of the clinical and electrical manifestations of the disease is well-documented." This brings into serious question the clinical significance of the EEG findings in the case he described. If biofeedback work shows nothing else, it does show that mental change can alter basic EEG patterns. Was electrical activity causing the mental status or vice versa?

It is striking that during the supposed epileptic impairment the patient was able to do the idiosyncratic and difficult task of skipping every other letter as she recited the alphabet backward. Are mental faculties curiously augmented in petit-mal status?

Another interesting aspect of the case is the winking or "irregular twitching." While I tentatively accept the possibly unwarranted assumption that the resident could not distinguish the two, I am nevertheless unwilling to consider irregular twitching of the eyes as always "organic." I have seen nonepileptic patients spontaneously demonstrate eye twitching during hypnosis. Further discouragement with the neurologic diagnosis in this case comes from the history of poor response to seizure medication.

How has Dr. Weissberg's diagnosis helped this patient? With the stigma of epilepsy substituted for the stigma of psychiatric disorder, this patient may go uncured for another 17 years on seizure medication, when perhaps hypnosis or biofeedback might help. I do not know whether to suggest psychodynamic psychotherapy also, since Dr. Weissberg gave no clues as to what lay behind the patient's description of "emotional upheaval," which she related to her seizures.

Finally, it is ironic that the paper expresses concern about the stigma of psychiatric hospitalization since the patient achieves no dignity in the case report until the positive EEG. The differential diagnosis seems to be: petit-mal status versus "crazy stripper." Thus we support the prejudices we decry.

KENNETH NAKDIMEN, M.D.
Jamaica, N.Y.

Dr. Weissberg Replies

SIR: The purpose of my report was to remind my colleagues of the existence and various presentations of petit-mal status. I hope my reply will satisfy Dr. Nakdimen's diverse and seemingly technical objections.

The EEG is an imperfect tool. Used in conjunction with clinical and historical evidence, however, it can verify diagnostic impressions. I caution to add that one can rarely confirm or deny the existence of an epileptic disorder with an EEG alone. It is unlikely that the disordered electrical activity by itself was "causing the mental status"; the neurophysiology of consciousness and cognition is incompletely understood. It is known that "psychological" events do alter brain processes, but the linkage between body and mind—the leap from soma to psyche—is not understood (1, 2). It is widely accepted that generalized seizures involve the centroencephalic systems (3), and I know of no instance where biofeedback techniques or mental activity provoked two to three cycles per second spike and wave discharges typical of petit-mal.

Response to seizure medication is not a test of neurologic diagnosis, and I am certain that Dr. Nakdimen is aware that there are many diseases in medicine that we diagnose but only imperfectly treat. I share his discouragement when faced with chronic diseases. I am glad to say, however, that petit-mal status usually responds to diazepam, as it did in the patient I described. Furthermore, the patient exhibited quite a good response to her medications after our first contact with her and, although not "cured," she was well controlled. Psychodynamic psychotherapy also seemed to be of benefit.

A careful rereading of the case will reveal that the patient was able to recite the alphabet backward skipping every other letter only after her EEG normalized. Therefore her "augmented" mental faculties were a result of the cessation of her seizures. Some patients (not the one reported) with

"markedly limited intellectual performance associated with severe paroxysmal abnormalities in the EEG, but with little else to indicate a continuing epileptic state" have improved markedly in cognitive abilities following medical or surgical treatment (4).

I am surprised that Dr. Nakdimen finds my concern about the stigma of psychiatric hospitalization ironic; I am sure he is aware that some patients suffering from epilepsy are also uneasy about their illness. Finally, I am glad to note that I share Dr. Nakdimen's conviction that irregular twitching of the eyes or winking is not always organic. Otherwise, we would find ourselves in not only diagnostic but also social dilemmas.

Denver, Colo.

A Positive View of the Chief Resident's Role

SIR: Having recently completed two years as a chief resident in psychiatry at the University of California, Los Angeles, Neuropsychiatric Institute, I was very interested in "The Chief Resident as Reluctant Staff Therapist" by Stephen A. Green, M.D. (October 1975 issue). Although I am no stranger to the quaint vocabulary of Kleinian and object-relations analytic schools, I found its use in a description of the functioning of a chief resident an academic exercise that did injustice to human interactions.

Like Dr. Green, I was often delayed in my hectic schedule by people seeking answers to difficult clinical problems, but not once did I feel the bite of "unconscious oral sadism." I was often called upon, as is any leader, to make decisions that affected people's work loads. Not infrequently, these people acted to protect their interests. Again, I managed to function without an "investigation of the entire staff's unconscious motivations." I discovered that people who work together often have frictions and fail to communicate. I do not recall having to "soothe and balance narcissism of staff members" or to interpret "unrealistic transference distortions" and "resistances." Unlike Dr. Green's obsession with unconscious fantasies, I found dealing with reality an excellent antidote for "becoming embroiled in struggles that seemingly came from nowhere."

Dr. Green is honest enough to describe his initial approach to his position as filled with "a flurry of obsessions and intellectualized activity" and expectations of the staff performing with "frenetic efficiency." He also bemoans his "progressive exclusion" from the unit, which he sees as a consequence of the "withdrawal" required by the job of chief resident in order to "preserve an effective therapeutic stance." I never experienced this progressive exclusion, and rather than the loneliness and isolation he described, I felt I worked in a warm, family-like atmosphere. I developed and maintain close friendships with many of my former colleagues. Rather than reawakening the anxieties of the first year of residency, I found my years as chief resident the most rewarding and satisfying in my training.

I suspect Dr. Green's findings are the result of his personal style of leadership and are not representative of the role of a chief resident. I believe that adherence to any dogma that turns people into "good" and "bad" objects is likely to create an image of a distant, aloof, uncaring leader. A Tavistock group model that was designed to intensify anxiety and transference might serve a particular group of patients well, but I see a strong argument against its application to the role of a chief resident in a setting already overwhelmed with anxieties.

The requirement that an effective leader be pragmatic seems ill served by slavish devotion to cutting and stretching reality to *any* theoretical model—and the more unsound the model, the poorer the fit.

JOSEPH R. SICIGNANO, M.D.
San Fernando, Calif.

Dr. Green Replies

SIR: It is surprising that Dr. Sicignano, a former leader of a therapeutic milieu, denies the existence of unconscious motivations in a psychiatric ward staff. His inability to recall the need to interpret staff resistances or transference distortions does not mean they were not present.

Dr. Sicignano feels I am "obsessed with unconscious fantasies" in suggesting that staff interactions do not always occur on the level of conscious awareness and criticizes my "slavish devotion" to a theoretical model. If he is referring to my belief that unacknowledged feelings, wishes, and needs derive from both patients and staff in a therapeutic milieu, he is correct. Unless this fact is recognized in psychiatric training and administration, the patient will ultimately suffer.

Bethesda, Md.

BOOK REVIEWS

Psychiatrists and Their Patients: A National Survey of Private Office Practice, *text by Judd Marmor, M.D.; based on a survey conducted by Patricia Scheidemandel and Charles Kanno; with commentaries by Gerridee Wheeler, James N. Sussex, Edward M. Kennedy, Zigmond Lebensohn, and Raymond Fink. Washington, D.C., Joint Information Service of the American Psychiatric Association and the National Association for Mental Health, 1975, 181 pp., $7.50.*

A 181-page book that contains 98 tables of statistics is difficult to read. I found myself wishing that Dr. Marmor's comments had been uninterrupted by the tables, that they had been relegated to an appendix. However, the material presented in the analyses perhaps justifies the rather ponderous method of presentation.

Stimulated by the current interest in national health insurance and the praiseworthy insistence that such plans provide adequate coverage for psychiatric care, the Joint Information Service of APA and the National Association for Mental Health (NAMH) set out to investigate the private practice of psychiatry, the patients receiving help from this sector, and the economics of the operation. With great persistence, Ms. Scheidemandel and Mr. Kanno were able to achieve a 73% return on questionnaires sent to 10% of the psychiatrists who reported in APA's 1970 census that they spent more than 15 hours a week in private office practice.

The data gathered in this way seemed so important that the Joint Information Service requested and (again, perhaps through admirable persistence) obtained an in-depth analysis by Judd Marmor and general comments from the president of NAMH, a U.S. Senator, an official of the Health Insurance Plan of Greater New York, and two distinguished psychiatrists. The result is a thought-provoking and informative survey of psychiatric practice that will be immensely useful to promoters of insurance plans and directors of training programs. Others will find themselves enlightened and at times surprised by the data presented.

Dr. Marmor notes the rather large proportion (29%) of psychoanalysts in the respondent group. Because psychoanalysts tend to see their patients more frequently and for longer periods of time, the use of psychoanalytic therapy as the treatment of choice raises some questions concerning the type of insurance coverage that could reasonably be provided. Full coverage would mean that a disproportionate amount of benefits would be used by comparatively few patients. Psychoanalysis as the treatment of choice should therefore be monitored by effective peer review systems. It would be equally unfair to deny patients a treatment modality that is optimum for them and to burden the majority of insured patients with an economic burden applicable to a few.

The survey also reveals that the "typical" patient of the private psychiatrist is not a bored, rich, idle housewife but a seriously ill person and that more men are represented in the patient population than is popularly believed. A surprising finding is the lack of children patients seen by the psychiatrists in the sample: only 2% of the patients seen by these psychiatrists were under the age of 10, and only 3% were between the ages of 10 and 14.

The commentaries following Dr. Marmor's extensive discussion provide additional dimensions to the picture. Both Ms. Wheeler and Senator Kennedy are concerned that insurance principles apply to the entire range of people who need psychiatric care and that the roles and responsibilities of psychiatrists in private practice working toward this goal be clarified. They agree that truly effective accountability is essential to avoid inequities.

Drs. Sussex and Lebensohn express their concern that quality of care be considered in any attempt to relate the practice of psychiatry to an economic system. In response to Dr. Marmor's stated surprise that ECT was administered to only .5% of the patients (a finding explained by the fact that these were outpatients and ECT therapy is usually an in-hospital procedure), Dr. Sussex and Dr. Lebensohn comment on the usefulness of this treatment modality in selected cases.

The insurance side of the picture is briefly presented by Raymond Fink, Ph.D. He points out that it is doubtful that national health insurance legislation could support the fiscal requirements of mental health insurance on a par with all other health services if a substantial proportion of these services were provided by private psychiatrists using their present modalities of care. It is this necessity for review of the current practices of private psychiatrists that inspired my comment about the importance of this survey to the training program director. Psychiatrists must learn to select treatment modalities in terms of patient needs, not in terms of preference or their own orientation. Dr. Lebensohn feels that general psychiatrists in private practice, "deeply steeped in the tradition of medicine," are best equipped to deal with the wide variety of psychiatric disorders.

This survey will help us all to evaluate the situation more accurately than has been possible in the past. The Joint Information Service is to be commended.

C.H. HARDIN BRANCH, M.D.
Santa Barbara, Calif.

The Psychological Birth of the Human Infant, *by Margaret S. Mahler, Fred Pine, and Anni Bergman. New York, N.Y., Basic Books, 1975, 293 pp., $15.00.*

The authors describe the infant as he proceeds from biological birth to psychological individuation. The senior author, a well-known psychoanalyst and theorist, has been dealing with the question of the preverbal development of the infant for many years. This work first began in the study of symbiotic psychosis and emerged into a study of the developmental process. The first time I heard Dr. Mahler speak, a discussant of her paper noted that the vocabulary had changed so considerably that it would be difficult for Freud

to understand it. The second discussant remarked that if this were true, perhaps the author should translate the language into terms that *even* Freud could understand.

Although the text is at times ponderous, the hypotheses are clear and the concepts sharply defined. To understand the intrapsychic development of preverbal children one must depend upon inferences from observations, and there will always be argument about the legitimacy of such inferences. The authors recognize this difficulty: "Although we cannot ultimately prove the correctness of such constructions, we nonetheless believe that they can be useful and we are committed to attempting their formulation" (p. 14).

The volume describes the research setting, providing floor plans and observational methods. There is a concluding section of summary and reflections with suggestions for research directions and inferences about possible further ways of proceeding with the research.

The main body of the volume consists of an exposition of the phases of the separation and individuation process:

> We see each phase as a time when a qualitatively different contribution is made to the individual's psychological growth. The normal autistic phase serves postnatal consolidation of extrauterine physiological growth. It promotes postfetal homeostasis. The normal symbiotic phase marks the all-important phylogenetic capacity of the human being to invest the mother within a vague dual unity that forms the primal soil from which all subsequent human relationships form. The separation-individuation phase is characterized by a steady increase in awareness of the separateness of the self and the "other" which coincides with the origins of a sense of self, of true object relationship, and of awareness of a reality in the outside world. (p. 48)

The authors identify the subphases of separation and individuation as follows: 1) differentiation in the development of the body image, 2) practicing, 3) rapprochement, and 4) consolidation of individuality and the beginnings of emotional object constancy. They recognize that individuals have their own styles and that there is no definitive timetable for this process, which takes place during the first three years of life. They also recognize the importance of normal mothering as a catalytic phenomenon:

> It is the specific unconscious need of the mother that activates out of the infant's infinite potentialities, those in particular that create for each mother "the child" who reflects her own *unique* and individual needs. This process takes place, of course, within the range of the child's innate endowments. (p. 60)

The fact that the authors indicate vulnerabilities in the developmental process and their consequent preventive implications is an important contribution. They also wisely include five detailed descriptions of children's subphase development so that clinicians may correlate their own experience with them. Although they make an effort to adapt biological principles and terminology (e.g., structure, epigenesis, and homeostasis) to metapsychology, they do not fully achieve the law of parsimony in biology. They also fail to relate to their discussion the work of others, such as that of Bowlby, Ainsworth, and the ethologists as well as the recent findings of competency in infancy.

It will be necessary to retest and correlate the authors' findings with current work, and the volume will provoke much discussion. Nonetheless, it will stand by itself as a classic of psychoanalytic research and investigation, shedding new light on the vicissitudes of child development. For those of us who have followed this work over the years and have taught these concepts, it is a welcome addition, and further contributions will be eagerly anticipated.

IRVING PHILIPS, M.D.
San Francisco, Calif.

Coverage and Utilization of Care for Mental Conditions Under Health Insurance—Various Studies, 1973–1974, *by Louis S. Reed, Ph.D. Washington, D.C., American Psychiatric Association, 1975, 80 pp., $4.00 (paper).*

This book represents Dr. Reed's final contribution to the collection and analysis of data demonstrating the feasibility of covering mental disorders under health insurance. It was published just a few days before his death in December 1975. To this work, as to all his many other writings in the field of health economics, Louis Reed brought great gifts: high intelligence, an ability to organize and make sense out of complex material, an unparalleled background in health insurance, and a remarkable zest for accumulating new knowledge.

Dr. Reed came to work for APA in 1970 as director of a project on the utilization and cost of psychiatric care under health insurance. He had just retired after a distinguished career in government and teaching in which he carried out in-depth research in the field of medical care with a view toward the eventual enactment of national health insurance. I do not think it an exaggeration to suggest that the book that resulted from the APA project (1) was given special attention by the insurance industry and the drafters of health insurance legislation because of Louis Reed's reputation for integrity and for rigorous, scholarly research. As one who was involved in that book as a coauthor, I can testify to Dr. Reed's skill in digging out material from myriad sources (some of which were less than eager to share their information), organizing it in an intelligent and coherent way, and analyzing it so it was understandable to those whose knowledge of health economics was not very deep.

This new book may be considered in one sense a supplement to the earlier one because it updates some of the information in that book, but all of the data are new. Six discrete studies were made by Dr. Reed (five of them under a contract with NIMH), and no effort was made to fit them into a cohesive package. However, together they make an impressive case for the inclusion of substantial mental illness benefits in health insurance plans.

Probably the most dramatic piece of evidence leading to this conclusion is the study of utilization of the high option of the Blue Cross and Blue Shield plan for federal employees, which is the largest private health insurance plan in the world and has essentially nondiscriminatory coverage of mental illness (although there are some special restrictions on care in private and public mental hospitals). The upward trend in utilization of benefits for mental disorders that has characterized this plan since its beginning in 1960 seems to have ended: utilization leveled off in 1973 and was slightly lower in 1974. In 1972 benefits for mental disorders constituted 7.3% of benefits for all conditions; in 1973 they constituted 7.4%; and in 1974 they were back down to 7.3%. This

study also gives detailed information on utilization patterns, with geographical, age, and sex breakdowns, duration of hospital stay, and distribution of persons undergoing office care for mental conditions by amount of physicians' charges covered.

Also of special interest in this book is the study describing the coverage of mental illness in employee health benefit plans. Nearly 150 plans, representing a broad cross section of American industry and including such giants as IBM, General Motors, Exxon, U.S. Steel, and American Airlines, were surveyed in regard to their coverage of mental illness. Almost all of the plans had some coverage of hospital care for mental conditions, and about two-thirds had the same coverage for mental as for other conditions when the care is given in general hospitals. In addition, about 90% of the plans covered some office care for general and/or mental conditions, and nearly 50% of these had nondiscriminatory mental illness coverage. The existence of this very substantial coverage makes the framers of most of the health insurance bills introduced in Congress appear unduly timid; one wonders if they are aware of how many Americans already have relatively good coverage of mental illness through the health insurance plans where they work.

The four other studies described in Dr. Reed's book cover the following areas: coverage of mental illness under the collective bargaining agreements of selected major unions; utilization of care for mental conditions under the Canadian health insurance program, which covers mental illness on the same basis as other illnesses; current benefits for hospital care of mental illness in Blue Cross plans; and data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

The six studies described in this book should prove extremely useful in winning improved mental health benefits in health insurance: through employer-employee-union plans, through state-mandated coverage, and eventually through national health insurance. If through research efforts such as this more patients who need mental health care are helped to pay for their treatment, the book will serve as a worthy memorial to a man who was not only an able health economist but a warm humanitarian.

Washington, D.C.

Emergencies in Child Psychiatry: Emotional Crises of Children, Youth and Their Families, *edited by Gilbert C. Morrison, M.D. Springfield, Ill., Charles C Thomas, 1975, 456 pp., $24.50.*

This book is a collection of 30 articles, 23 of which have been previously published. Most of the 22 contributing authors are highly respected teachers of child psychiatry.

Following a captivating essay that illustrates views of childhood portrayed in literature, the introductory section begins with a discussion of crisis intervention versus long-term intensive treatment. The hope is expressed that someday the clinicians dedicated to each ideological position will stop debating maximum versus minimum in favor of optimum treatment. May the planners and funders please take note.

Defining emergencies in child psychiatry is likely to be a matter of some interest to readers familiar with this subject, who will already have found many less than satisfactory attempts at definition. These authors point out that most emergencies present as intolerable behavioral problems but that developmental and emotional disturbances were present much earlier. At any age, homicidal and suicidal threats and acute decompensating psychotic reactions constitute emergencies. They constitute a threat to biological integrity or life, a condition commonly cited in defining a medical or psychiatric emergency.

Acute school phobia, generally considered an emergency by child psychiatrists, does not constitute such a threat. It interferes in a major way with consistent ego development, however, and that theme is developed by the editor to reach the following definition of an emergency in child psychiatry: "that situation in which the significant adults around the child can no longer help him master his anxiety and can no longer provide temporary ego support and controls."

The second section of the book, Crisis Intervention, Brief Treatment, and Early Prevention, contains 7 chapters on these subjects. The third section, Clinical Experience and Research, includes discussions of depression, suicidal behaviors, aggressive behaviors, school phobia, and emergency consultations on pediatric wards. The fourth section, Treatment Planning, has more chapters on crisis intervention as well as reports on drug abuse and drug therapy.

A common criticism of volumes of collected papers by several authors is that the papers may not all be related to the central theme. That must be said of this volume, but it is the only disappointment I found. The papers on primary prevention and intensive diagnosis and treatment, although laudable, are only peripherally pertinent to a discussion of emergencies. A discussion of psychosocial factors in adolescent pregnancies is even less so, particularly because this one was written long before the Supreme Court decision on abortion of January 1973.

Perhaps the subtitle of this book, *Emotional Crises of Children, Youth and their Families*, more accurately describes its content than the title. As is pointed out in the book, " 'Crisis' is not the same as 'emergency.' " If taken as a volume on crises, it will be of value and interest to all mental health professionals—a book in which one reads a chapter or two at a time but which is frequently taken from the shelf to reread.

JOSEPH M. GREEN, M.D.
Tucson, Ariz.

The Future Role of the State Hospital, *edited by Jack Zusman and Elmer F. Bertsch. Lexington, Mass., Lexington Books (D.C. Heath and Co.), 1975, 390 pp., no price listed.*

The words "state hospital" often conjure up an image of things—massive buildings or isolated grounds—rather than an image of people—patients and personnel doing things and currently in the throes of role change. The role change is complex because of the great variation among state hospitals in leadership, location, professional practices, patient populations, political relationships, community images, and economic realities. This book, which scans the many issues related to change in state hospitals and successfully serves to

emphasize function over structure, reports on a conference held under the leadership of the department of psychiatry of the State University of New York at Buffalo. The editors take the rich content of the individual contributions and give them a meaningful continuity and a balanced perspective.

Demone and Schulberg provide a clear view of the new human services network as the context for the future role of the state hospital. Because community-based mental health services are emerging as viable cores for these networks, state hospitals that are linked to community centers are likely to emerge with new vitality and different functions. On the other hand, state hospitals that are isolated from community programs are assigned the kind of bleak future they may have earned through their rigid adherence to mental status, labels, and pills as the only or primary methods for human problem solving.

The stance that state hospitals must either change or close is continued in the next section of the book, which considers outside pressures. Here the increasing impact of constitutional requirements in regard to the management of the mentally ill are made lucid by Judge Flashner. One's constitutional right to liberty is shown to override such other legal issues as treatability and dangerousness. The impact of litigation on the state hospital is neatly packaged by Bruce Ennis, who sees the state hospital as on its way out. However, Peszke demands that laws be ultimately workable at the level of clinical practice.

A review of the newer treatment modalities presents the constructive impact of behavioral approaches in dealing with regressed patients. Cannon stresses the need to prepare patients as well as staff members of both state hospitals and halfway houses for the transitional crises that emerge when patients are placed in the community.

A major section of the book deals with internal pressures for change by presenting programs at state hospitals that have humanized their patients and staff, established new links with programs in the community, established their own programs in the community, and used empty space in the hospital for other human services agencies. This section includes a rich sampling of experience from rural and urban programs. For example, Mesmer's description of the community program of Warren State Hospital in Pennsylvania demonstrates how outreach programs represent roads to survival. From the standpoint of urban state hospital services, Talbott is worth quoting:

> The state hospitals' long standing commitment to the severely mentally ill, coupled with the widespread lack of interest by others in dealing with such impoverished people, militates against an early demise.

Cole's personal and colorful account of his experience at Boston State Hospital describes what happens when a superintendent juggles demands from every direction. Another chapter deals with recent developments in public mental health care in France and concepts of the state hospital in the U.S.S.R. These enlighten the reader to the fact that complex bureaucratic binds that serve to perpetuate the status quo in mental health service delivery systems exist everywhere.

The opinions given in this book are generously supported by statistical tables, many of them from the Biometry Branch of NIMH, which through the years has helped to make planning of state hospitals less speculative and rhetorical.

Conferences and books about conferences are successful only if their information generates new concepts and methods. This book succeeds because it highlights the need to find and solve problems relating to the future role of the state hospital. As Erickson asked (1), "Is neglecting the traditional solution [the state hospital] leading to neglect of the problem . . . that makes entry into an institution necessary?" In agreement with Arnhoff's recent warning concerning abandonment of state hospital programs (2), this book conveys the message that a soaring interest in closing state hospitals is not necessarily paralleled by deeper concern or clear plans for the future of the people the hospital serves. New programs are needed to assist in problem solving with the regressed mentally ill, the public offender, the chemically disabled, the deviant, the alienated, and the socially dependent person.

When the walls of state hospitals built with the zeal of reform in the 1840s have crumbled and the dust of the 1970s' reform movement has settled, we may still have failed to deal effectively with the severely regressed or damaged person whose psychosocial functioning is fragile.

To me, this book conveys the message that state hospitals will close, but their trappings may be hung in other halls and their old rituals may be performed in the community without really accomplishing a great deal for the citizen. It urges all those who are concerned with the role of the state hospital to focus on programs for people. Unless this is done now, we may look back from some point in the future and remember with dismay the warning best expressed by the French: "Plus ça change, plus c'est la même chose."

JAMES W. DYKENS, M.D.
Concord, N.H.

The Care and Training of the Mentally Handicapped: A Manual for the Caring Professions, *by Charles H. Hallas, S.R.N., William I. Fraser, M.D., and Ronald C. MacGillivray, M.B., D.P.M. Bristol, England, John Wright and Sons (Baltimore, Md., Williams & Wilkins, exclusive U.S. distributor), 1974, 269 pp., $18.75.*

This is the fifth edition of a textbook and manual first published in 1958. It is written for nurses and child-care personnel and concerns the care and management of mentally handicapped individuals. This edition is important because it is the first in which the senior author, a nurse, has had the assistance of two psychiatrists as coauthors. As a result, this edition has an up-to-date emphasis on multidisciplinary and community approaches. The legacy of the four previous editions provides the reader with a perspective that combines the new and the traditional.

Although the book is addressed to professionals in England, Scotland, and Wales, many of its principles and discussions are applicable in other nations as well. In Great Britain the diagnosis of mental handicap is applied to persons who would be classified under the diagnosis of mental retardation in *DSM-II* (1).

The authors provide historical comments on the changes of opinions concerning concepts of care for the mentally handicapped. They endorse the modern emphasis on non-

institutionalization of the mentally retarded, but they caution that this trend may become overemphasized to the point that children who need to be separated from their families for a period of time may not be given this opportunity because of the tendency of some professionals to follow the latest ideas to the extreme.

The chapter outlining diagnostic categories of mental handicap is written with competence. The chapters on patient and family management, written specifically for the staffs of institutions, are also of particular value. For those interested, the description of the recent health acts in Great Britain and Scotland provide a detailed review of current developments there.

In general, this volume would make a good text for nurses, aides, and child-care workers in training as well as a good manual for in-service programs. It provides adequate references for particular problems. The reader in the United States will sometimes be amused by parochialisms on the part of the British authors, including occasional uncomplimentary references to American culture. Also, the old and the new are sometimes strikingly juxtaposed. For example, a section giving detailed instructions for the nursing sisters on the making and stoking of coal fires on the wards is followed by a description of the latest techniques of behavior modification as applied to patient management.

The style of writing varies from chapter to chapter, a result, one would guess, of the difficult process of revision that had to take into account the changes in professional and cultural attitudes toward the mentally retarded in the last decade.

Frames and Cages: The Repertory Grid Approach to Human Understanding, *by Anthony Ryle. New York, N.Y., International Universities Press, 1975, 146 pp., $11.50.*

The repertory grid technique stems from the late George Kelly's theory of personal constructs. For Kelly, the key to understanding the personality of an individual lies in the representations or models of the world that the individual has adopted as a result of his experience with it. Access to this personal structure of constructs and values is attained by asking the person to rate what Kelly termed "elements," such as significant others, the self, objects, situations, or concepts, on a series of "constructs," which consist of bipolar scales, such as timid/bold, attractive/unattractive, and desirable/undesirable. These ratings may then be related on a grid that offers a two-dimensional spatial representation or projection of the interrelationship between elements and constructs. The grid may result from a simple empirical analysis of the ratings or from the application of highly sophisticated mathematical procedures.

The technique is a flexible one because it calls for the clinician to select those elements and constructs which he feels are pertinent to the patient's (or client's) problems. Thus a patient with disturbed family relations might be asked to rate significant family members and himself on such dimensions as friendly/hostile, dominant/submissive, and pleasing/disturbing. The repertory grid as a technique is independent of the theoretical framework within which it is applied. Thus, although Ryle's orientation is psychoanalytic, his systematic position does not alter the basic repertory grid methodology. Rather, it expresses itself in the choice of elements and constructs to be used and in the clinical interpretation of findings.

Ryle begins with a critical assessment of Kelly's philosophy, followed by an exposition of the repertory grid technique. He provides numerous case examples and cites the experimental literature, albeit not extensively. He then integrates all of this with his personal analytic position. Thus the book essentially consists of two intermingled parts: a clear exposition of the repertory grid technique and an equally clear development of the author's psychoanalytic approach.

There can be little disagreement with the explanation of the technique. Anyone should understand and be able to use the grid technique after reading this book. However, some disagreement may inevitably arise with Ryle's psychoanalytic interpretation. As a theoretician he is stimulating, but he writes with a definitely authoritative stance that makes few concessions to opposing views. One wonders whether his strong criticism of Kelly's thinking as sometimes "naive, overstated, and overpolemical" may not boomerang.

The book is addressed primarily to those who are professionally concerned with the assisting and measuring of change in individuals with personal difficulties. It is clearly written but at a professional level that demands careful, attentive reading. It merits the interested clinician's attention, both as an introduction to the repertory grid technique and as a thoughtful integration of Kelly's position with the psychoanalytic orientation of the author.

WILLIAM A. HUNT, PH.D.
Chicago, Ill.

LSD—A Total Study, *edited by D.V. Siva Sankar. Westbury, N.Y., PJD Publications, 1975, 922 pp., $29.75.*

In the eighteenth century it was fashionable for men of letters to write compendia on natural history. These scrapbooks often contained a miscellany of observation, experience, hearsay, and fantasy. Because the authors were well grounded in religious learning, the volumes also included religious allegory and citation. *LSD—A Total Study* is such an effort for our century; it combines biochemical, pharmacological, physiological, and historical information with anecdotes, opinions, and popular statements.

This compilation is large (922 pages); 73% of it was written by Dr. Sankar and the rest by such students of hallucinogens as Harold Abramson, Roland Fischer, Leonide Goldstein, and John Smythies. In addition to the technical sections, there are chapters devoted to social and legal issues. The appendices include a classification of psychotropic drugs, a list of legal penalties in New York State and California, and an index of slang terminology. Reference lists follow each chapter; these are in the style of chemical journals with authors, journal, volume, and first page number given but without the article's title.

The volume's strength is in its chemical details, particularly in the formulas for congeners of hallucinogens and identifi-

cation of LSD in fluids. There is also value in the miscellany that appears in the figures (many delightful drawings of opium use, for example) and in the citations concerning a wide range of drugs of abuse. One finds such tidbits as "Mimosa Hastibus: a hallucinogen used by Brazilian Indians; contains dimethyltryptamine" and "Fly Agaric: consumed in Siberia especially by Koryaks. During carousing men stayed intoxicated for several days at a time, even drinking their own urine to prolong the effects! Used in Shamanistic rituals."

It is not clear what posture Dr. Sankar wishes to take with regard to the use of LSD in psychiatry. In his epilogue he warns against LSD use ("LSD is a very potent drug and as such its use could certainly result in damage that cannot be adequately estimated at this time"); suggests uses for which the text shows little support ("LSD has enhanced appreciation of sight and sound, including music, on occasions . . . [and] increased religious consciousness and mystic abilities"); and exhorts ("With all the evidence indicating the undesirable effects of LSD, I wish to emphasize . . . it has opened the eyes of our society to many problems. In so doing, the users themselves became victims of the use"). There are references to Oriental and Hindu philosophy in the text, suggesting that LSD was selected as the topic for this volume more for its association with mysticism than its salience for modern psychiatry.

The volume is commendable as a source of miscellany concerning LSD and other hallucinogens. It is a useful addition to resource libraries, where it would best be located among volumes dedicated to the chemistry, pharmacology, and ethnopharmacognosy of drugs.

MAX FINK, M.D.
Stony Brook, N.Y.

The Theory and Practice of Group Psychotherapy, 2nd ed., *by Irvin D. Yalom. New York, N.Y., Basic Books, 1975, 522 pp., $12.50.*

Dr. Yalom sets the tone of the second edition of his book by stating that psychotherapists who examine their basic view of man soon discover they are and always have been existentialists. Presumptions such as this abound in the volume, and, although the author states that this book is not the place for a treatise on the existential approach in psychiatry, he offers a good deal more about existentialism than the reader of a book on group psychotherapy may have bargained for.

Dr. Yalom displays a tendency toward overstatement that is confusing. One wonders why it is necessary to describe the entire body of knowledge regarding psychiatric diagnosis as "not only errorful but offensive"—a view with which most psychiatrists would disagree. Is Freudian psychology truly "materialistic" and "antivitalistic"? Is concurrent individual and group therapy "neither necessary nor helpful"? Are structured exercises such as those used in behavioral group therapy "undesirable and antitherapeutic"? And so on. The author shows a strong urge to separate himself from any psychoanalytic contamination, seriously questions genetic causality, minimizes early experience and its effects on adult behavior and character structure, and believes that groups should be primarily ahistoric and should not "water down the tragedy of life," as they too often do, in his opinion.

In addition to speaking out on theoretical issues, Dr. Yalom incorporates into this book many of his research findings on encounter groups in an effort to update the volume. He measured outcome and the relationship of outcome to leader technique and found, among other things, that most encounter group participants are generally positively inclined toward the experience and believe it to have been useful. A word of caution to the beginning group therapist is in order here. Many of the clinical vignettes and conclusions scattered throughout the book are drawn from this research and other short-term encounter group experiences in which the groups were composed of normal people who required a type of education. The therapy group, on the other hand, is composed of persons who are mentally ill and who seek to have their disorders cured or, at least, ameliorated. Although the two types of groups have some things in common, there are important differences. A technique used or an outcome realized in one type of group is not necessarily valid for the other.

A variety of group therapy approaches is available to the clinician, and no one has been able to demonstrate the superiority of one method over another. Dr. Yalom favors the here-and-now approach and does not pay enough attention to the many alternative methods of group treatment. Indeed, he shows a tendency to be hypercritical of other methods, as in his description of transactional group psychotherapy as simplistic and nonproductive. One wonders if the time is not past when a single author can discuss the variety of group approaches with sufficient depth and objectivity to do justice to this rapidly expanding field.

In this book's first edition, which I also reviewed, Dr. Yalom's discussion of the curative factors at work in every therapy group—irrespective of the therapist's technique or theoretical orientation—was of value, as were chapters on the selection and preparation of patients for a group therapy experience, on the composition and organization of a group, and on problem patients and group therapy dropouts. Fortunately, these chapters, which constitute a large part of the second edition, remain virtually intact. Those who are thinking of buying the new edition should be aware that they will get a great deal of the author's personal views of psychiatry in addition to a book on group psychotherapy.

BENJAMIN J. SADOCK, M.D.
New York, N.Y.

The Dream in Psychoanalysis, revised ed., *by Leon L. Altman, M.D. New York, N.Y., International Universities Press, 1975, 272 pp., $12.50.*

Dr. Altman has written a short, clear description of the clinical and theoretical use of the dream in psychoanalysis. He thinks analysts and analytic students do not currently use the dream as fully and as effectively as they might. The author carefully selects clinical examples to illustrate the dream's use in analyzing resistance, transference, underlying impulses, homosexual libido, and oedipal conflict. There is a chapter on how the dream can be used to measure adaptive ego and therapeutic progress as well as a description of how Dr. Altman uses his own dreams to understand countertransference and to better understand his patients.

The author carefully describes the dream, the associative material, the analyst's unspoken thoughts, and finally his interpretation. He carefully explains that not all dreams can be analyzed; he presents only carefully selected dreams that

were understood. In psychoanalysis, dreams that cannot be understood outnumber those which can be analyzed by far.

This book belongs in the hands of the analyst and the budding analyst. It is also clinically useful and can be profitably read by therapists with a marginal interest in psychoanalysis.

FRANK KLINE, M.D.
Los Angeles, Calif.

Chemical Coping: A Report on Legal Drug Use in the United States, *by Carl D. Chambers, James A. Inciardi, and Harvey A. Siegal. New York, N.Y., Spectrum Publications (Halsted Press, John Wiley & Sons, distributor), 1975, 154 pp., no price listed.*

The goals of ascertaining the extent of use of legal psychoactive drugs in this country and learning something about the people who use them are to be applauded. This book is divided into four parts: Prescriptive Drugs, Over the Counter (OTC) Psychoactive Drugs, Alcohol, and a Summary that includes excellent abstracts of 15 recent publications. However, there is no bibliography, which limits the usefulness of the book for professionals. Each section contains a description of the psychological and physiological effects of the drug under consideration. Although this is not of sufficient depth for the knowledgeable professional, it will interest lay readers.

The information in the book represents the results of personal interviews of unspecified length and format with 30,000 people from the age of 13 to over 50 in 16 states, including Washington, D.C. No western coastal state was included. The authors assure us that the higher rates of drug use reported in the states excluded would not be "so high as to significantly alter the projections we are proposing." No information about the selection of sample or the numbers that came from any area of the country are included. It is impossible to tell whether the sample of 30,000 included any or all of the 7,500 people surveyed in New York State. The latter survey is the basis of a "special analysis concerning the rate of regular [drug] use within various worker categories [which makes] it possible to rank the regular users of the drugs."

The statistical analysis is presented by projecting survey data for the total population older than 13 in terms of age, sex, socioeconomic status, race, and occupation. The analysis highlights the fact that the majority of the drug using population are women; the exception is that men younger than 25 use more prescription and OTC stimulants. There appears to be little difference between races with regard to use of barbiturates, major tranquilizers, amphetamines, and OTC stimulants and tranquilizers. Blacks are significantly overrepresented among users of nonbarbiturate sedatives, and whites are overrepresented among users of minor tranquilizers, OTC tranquilizers, and antidepressants. Housewives, who are major drug users according to the data for the whole sample, do not rank as high in drug use in the more detailed study of occupation and drug use performed for the 7,500 respondents of New York State.

The number of typographical errors in this book is considerable. Therefore, questions have to be raised about the care with which tabulations were presented. Obvious errors exist on page 124 (4.9% should read 49%) and on page 122 (the legend for a bar graph is inaccurate). In the course of outlining relevant points to present in this review, I prepared a table from the data given in the text. When I compared my table with those presented on pages 51–53 and page 87, I noted 5 discrepancies. In addition, there were 14 areas in which data presented in one section of the book were not described in other, comparable sections.

The book would be of more interest if it moved from emphasizing the demographic to considering a broader range of topics, e.g., speculating on reasons why people who use one drug choose to use another as well; why women seek more medication than men; or why major tranquilizers were associated with a higher rate of alcoholic use than minor tranquilizers or sedatives. Critical consideration of the respondents' answers is also missing in at least one area: 71.4% of regular users of amphetamines for diet control stated they never used the drug while on the job; it is conceivable that the respondents took sustained release capsules early in the day so that they had "drug activity" even though additional pills were not taken.

Because the authors had an opportunity to gather data on a national rather than a local level, it would have been of interest to learn about the drug use habits of families, the relationship between legal and illicit drug use, and the personality patterns of drug users (1–3).

The importance of this book lies in its provision of basic epidemiological data. The simple straightforward style with which it is written makes it possible to skim it quickly and gain a general understanding of the subject. One only wishes that the authors had included better data as to the representativeness of their sample and given more thought to the implications of their findings, rather than conclude, "We suggest that social planners . . . begin to determine what 'the problem' really is."

Stone Age Crisis: A Psychiatric Appraisal, *by B.G. Burton-Bradley. Nashville, Tenn., Vanderbilt University Press, 1975, 121 pp., $8.95.*

Dr. Burton-Bradley draws on his 15 years of experience as the only psychiatrist in Papua New Guinea for this book. The original papers were presented at Vanderbilt University while he was the Abraham Flexner lecturer in 1973.

The initial chapter describes the transformation of a culture from the stone age to the twentieth century in the brief span of one generation. The author subsequently focuses on specific psychiatric entities, including the cargo cult, suicide, and amok. He then proceeds to examine the people, the problems of mixed races and mixed blood, and the type of psychiatry practiced in Papua New Guinea.

Burton-Bradley describes the cargo cult as a pathological group process in which the leader is usually a psychotic indi-

vidual who promises to deliver a cargo that will change the status and life of his followers. The author shows through case examples that this behavior often leads to psychotic homicide or suicide.

Dr. Burton-Bradley notes the difficulty of defining and diagnosing the phenomenon of suicide. He contrasts the means of suicide in New Guinea to those in more developed nations; popular modes include poisoning by derris root and running amok. He theorizes that the explosive reaction referred to as amok is seriously influenced by group expectancies and discusses the psychogenic versus the organic as causes of amok, concluding that the organic explanation is a red herring with no scientific validity.

This book is easily read and provides a transcultural view of psychiatric illnesses. I found it to be concise and free of the ambivalence typical of many psychiatric textbooks. I would recommend it to psychiatrists for both its informative and its transcultural content.

The Role of Diagnosis in Psychiatry, *by R.E. Kendell, M.D. Oxford, England, Blackwell Scientific Publications (Philadelphia, Pa., J.B. Lippincott Co., distributor), 1975, 166 pp., $14.00 (paper).*

This short book undertakes the task of discussing the pros and cons of diagnosis in psychiatry. On the disadvantage side of the controversy the author discusses the disease concept, the harmful effects of labels (including physicians' treating diseases instead of people), and other related issues. The major point made on the advantage side of the ledger is that diagnosis improves communication.

In the middle of the book the author discusses reliability and validity, disease entities in psychiatry, and *ICD-8* (1). The final three chapters broach the subject of defining criteria for different disease entities; the last chapter is titled "Diagnosis by Computer."

While reading this book one has a response similar to that one gets from having to fill out the Medicare-Medicaid forms to justify admission of a patient. After reading this book one has a better understanding of the principles behind checklist diagnoses. With the increasing demand for accountability in medicine, this book offers some assistance in the task of formulating a means of objective diagnosis. It allows the reader to formulate his or her thinking in an active rather than a reactive manner.

Overall, this is an interesting book that may prove timely in that it may assist the reader to make suggestions to APA's Committee on Nomenclature and Statistics, which is working on the third edition of *DSM* (2) (planned for completion in 1978).

Medical Sociology: A General Systems Approach, *by Leon S. Robertson, Ph.D., and Margaret C. Heagarty, M.D. Chicago, Ill., Nelson-Hall, 1975, 208 pp., $11.00.*

This textbook of medical sociology devotes eight chapters to a rather detached but comprehensive view of various aspects of medicine: the making of a patient, the making of a physician, the multiple relationships of the patient and physician, and the relationship of both to the family, the community, the hospital, the local and central government, and, finally, the international scene.

As an addition to this rather standard sociological approach, the first chapter is devoted to a good, concise description of general systems theory, and the final chapter is a generalized application of systems methods to the sociological material.

My overall reaction to this book is positive. Although it contains no specifically psychiatric material, it has a great deal that will interest the psychiatrist. It is carefully written and has a good list of references, a name index, and a subject index. One hopes that the authors will bring a closer integration of systems theory with their sociological material in a later book.

The Innovative Psychological Therapies: Critical and Creative Contributions, *edited by Richard M. Suinn and Richard G. Weigel. New York, N.Y., Harper & Row, 1975, 242 pp., $7.95 (paper).*

This book consists of a group of articles selected by two college professors as representative of the newer forms of psychotherapy. The editors' goal was to provide college students with samples of similar size and style. Most of these are garnished with scientific vocabulary, but the result is rather bland. One will find pieces on behavior therapy, operant conditioning, coverant control, aversive control, anxiety management, Gestalt groups, nude marathons, touching, saturation, drug addiction therapy, group exercises, the use of videotape in group therapy, free clinics, campus crisis centers, psychodrama, milieu therapy, an analysis of hospital discharge rates, and paraprofessional counseling.

At least four of the articles deserve special mention: Ayllon and Azrin on a token economy, Mintz on touching, Bassin on Daytop Village, and Russell on group exercises. The first is a good example of clinical description and explication of treatment goals; the second is a reflective essay about intimacy phrased in psychoanalytic terms; the third is a warm, candid account of drug addiction treatment; and the fourth enumerates the many techniques group leaders use along with the objective of each maneuver.

The overall flavor of this sampler can be seen in the following statement of Kanfer and Phillips:

> But whenever undue emphasis is placed on a particular technique, be it hypnosis, psychoanalysis, psychosurgery, or use of tranquilizers, there is a serious danger that faith instead of reason becomes the guiding criterion.

The bias reflected in this collection appears to be toward activism. Notably absent, although "innovative," are Trans-

cendental Meditation, transactional analysis, and biofeedback. This text does not pretend to be an exhaustive and definitive college survey course, but it should provide some nourishment without dulling the taste of its readers for heavier fare and full digestion.

ROBERT VOSBURG, M.D.
Hanover, N.H.

Re-Visioning Psychology, *by James Hillman. New York, N.Y., Harper & Row, 1975, 260 pp., $12.50.*

This book, the most comprehensive expression of Hillman's thought to date, was created from his 1972 Terry Lectures given at Yale University. Carl Jung had given the Terry Lectures 35 years earlier on the subject of psychology and religion. Jung documented the reality of the unconscious and the power of the natural symbols emerging. Hillman tackles somewhat the same subject from the vantage point that time has given and ranges farther afield, from Heraclitus to Freud, Jung, and beyond. His book is so rich in content and imaginative possibilities that a review cannot do it justice.

Hillman describes his aim as "an attempt at a psychology of soul, an essay in re-visioning psychology from the point of view of soul." His concern is "soul making," and he uses the word "soul" rather synonymously with "anima," the archetype that relates one to the deep unconscious and its wealth of images. As the soul provides a connection to the God-image, we can understand the author's statement, "A re-vision of psychology means recognizing that psychology does not take place without religion, because there is always a God in what we are doing." For Hillman there are many gods affecting the soul, a polytheistic position, and man's abode is a Jamesian pluralistic universe.

The author delineates four functions of the soul: personifying, pathologizing, psychologizing, and dehumanizing.

To describe the personifying function Hillman goes back to the Greeks, who personified the psychic powers and gave them names, shrines, and altars. He chooses this word to keep close to the image per se and its impact. He would say trust and have faith in the imagery rather than interpret, discipline, or form defenses against it.

On pathologizing Hillman states, "Without psychopathology there is no wholeness." Soul, archetype, and myth insist on pathologizing, i.e., forming images of sickness. Hillman searches for the psychological necessity in this. Ultimately it is toward death that the soul leads, but there can be symbolic deaths and new beginnings on the road toward building one's own unique death. Again Hillman advocates going with the imagery rather than treating, correcting, or medicating it away.

In his chapter on psychologizing Hillman searches for the gods in our ideas and how the soul provides the tools to have insight into its own purpose. He argues against literalism, which blocks understanding of the soul's symbolic expression.

In the final chapter, titled "Dehumanizing or Soul Making," Hillman points out that modern psychology "has been obsessed by one overvalued idea: Man." He states that "we refuse to admit . . . that human reality is dependent on the realities that take place in the soul." Therefore, he strikes out against the humanistic psychologies, which he says have softened "our sensitivity to archetypal realities and keeps our perceptions too shortsighted, focused only on ourselves and neighbor."

This book is austere, painful, provocative, and challenging. It is concerned with the depths of eternal verities. It is a good book for any therapist of any school because it encourages self-reflection regarding one's own life and how one works with people.

On the questionable side there seems to be a certain imbalance in its content. Although there is a timely and compensatory emphasis on soul, there is a de-emphasis of ego and of the central "self archetype." The relative neglect of the self archetype suggests that Hillman sees this archetype differently from many of his colleagues, who do not see it as a "monotheistic model" but as a basic structure of the psyche that presides over the birth of the ego and regulates its development from cradle to grave.

This book may well be controversial even within the Jungian community from which it originates. However, if it incites reflection and open-eyed review of our condition and options, its purpose will be achieved.

Position Statement on Mental Health Representation in Governance and Staffing of Health Systems Agencies

This statement was approved by the Assembly of District Branches at its November 4–5, 1975, meeting and by the Board of Trustees at its December 5–6, 1975, meeting, upon recommendation of the Council on National Affairs. It was prepared by the Task Force on Comprehensive Health Planning.[1]

THE NATIONAL HEALTH PLANNING and Resources Development Act of 1974 (Public Law 93-641) establishes at the local, state, and national levels organizational entities that will govern the planning, development, and allocation of all health resources to come. The objectives of the legislation are to develop a more rational system that can equitably, efficiently, and effectively utilize scarce health resources. The legislative guidelines call for increased services to underserved populations, consolidation of multilevel services in order to improve service accessibility and availability, training and redistribution of health manpower, development of mechanisms for cost containment and quality assurance, development of preventive services, and control over capital construction costs.

The House Interstate and Foreign Commerce Committee report on the health planning legislation (1) establishes legislative intent that health planning include activities such as mental health planning and that expertise in this area be represented to the maximum possible extent. It is essential that mental health not be regarded, for the purposes of this legislation, as a special interest. It must be viewed as a primary component of total health planning and service delivery and thus of central importance and focus to the development of Health Systems Agencies and the other organizational elements called for under this legislation. It is vital that persons with mental health knowledge, experience, and capability be represented on the governing bodies of Health Systems Agencies and the State Health Coordinating Councils that will govern the State Health Planning and Development Agencies. In addition, staff with experience and capability in the field of mental health planning must be part of the total staff of each organizational element required by this legislation.

The field of mental health, broadly defined, includes the areas of emotional disturbance and stress, mental disabilities, substance abuse, and developmental disabilities. Since 1963, with the passage of the community mental health centers legislation, mental health systems at local, state, and national levels have concerned themselves with developing organized systems for health care delivery and planning that have been directed at the very objectives now enunciated and espoused under the present legislation, i.e., increased services to the underserved, development of primary prevention programs, improved availability and accessibility of services through consolidation of programs, expanded utilization and training of manpower, utilization review and cost containment, and the integral involvement of consumers in planning and development of mental health programs. Thus the mental health system in the United States probably has the greatest degree of experience of any organized health delivery system in actually dealing with the issues keyed to the success of this legislation.

Implicit in the development of mental health programs has been the attempt to approach the individual as well as the development of health care services in a holistic manner—which includes consideration of essential environmental factors. Thus mental health programs have been intimately involved and intertwined in the delivery of physical health services. It is estimated that anywhere from 50% to 70% of individuals presenting with an initial presumptive diagnosis of physical illness are, in fact, suffering from primary or secondary emotional problems. The development of a mental health component generic to the delivery of all health services has become recognized as an essential element of any health care delivery system. Studies conducted in organized group health programs have shown the positive cost benefits as well as the patient benefits that can be achieved in incorporating a mental health orientation into the overall health planning and delivery process (2, 3).

On the basis of cost of services and numbers of persons receiving health services, it is essential that there be mental health representation both in governance and staffing. One of every four persons in the United States receives health services for the treatment of a mental health problem (4). If we consider physical health services in which there are primary or secondary mental health problems, this figure would be doubled or tripled. Thirty percent of hospital beds utilized in the United States are for mental health conditions (4–6).

The cost of direct health services for the fiscal year 1975 was $118 billion. This represents a figure approaching one-tenth of the gross national product (7). Fourteen percent was expended for direct mental health services (4). If the cost of treatment services for substance abuse and developmental

[1]The Task Force on Comprehensive Health Planning included Robert L. Williams, M.D., chairperson, James Harris, M.D., Marvin E. Perkins, M.D., Edward G. Long, M.D., George F. Wilson, M.D., Howard Gurevitz, M.D., and Falk Fellows S. Charles Schulz, M.D., and John O'Neal, M.D.

disabilities were added, this figure would be doubled. In addition, indirect costs due to factors such as loss of productivity and income, increased social dependency, and crime and delinquency have been estimated to increase direct service expenditures by 100%. Thus in 1975, it can be conservatively surmised that the United States spent approximately $100 billion for direct services and indirect costs related to mental disabilities, emotional disturbances, alcoholism, drug abuse, and developmental disabilities.

The field of mental health has taken a position and orientation by interfacing with other human services such as education, corrections, and social welfare, which provide vital opportunities for early detection and intervention in situations that can lead to mental, physical, and emotional disturbances. These interfaces place the mental health system in a very advantageous position to deal knowledgeably with the planning of health services and programs that are community oriented, geared toward prevention and early intervention of disabilities, emphasize ambulatory care and deinstitutionalization, and have the capacity to provide services to the chronically ill.

For the foregoing reasons, we urge that there be mental health representation in the governance of each jurisdictional level called for under this legislation. Such representation on boards of governance must reflect the essential quality of mental health planning to the entire field of health planning and service delivery. It must also be adequate and in proportion to the time, money, and experience invested in these mental health efforts.

Furthermore, staff with demonstrated capability and expertise in dealing with matters related to mental health planning should be available to these bodies. It is recommended that at least one staff person for each health service area be specially qualified through experience and training in the field of mental health planning and program development.

These recommendations are forwarded in light of Congressional intent that both mental health planning activities and expertise be an integral part of total health planning and service delivery.

Position Statement on the Quality of Life

This statement was approved by the Board of Trustees at its December 5–6, 1975, meeting upon recommendation of the Council on National Affairs. It was prepared by the Task Force on Ecopsychiatric Data Base.[1]

THE MEDICAL specialty of psychiatry is concerned with psychosocial issues as they impinge on individual growth and development and the achievement of positive mental health. Accordingly, psychiatry cannot be relieved of sharing responsibility with other human services for advancing understanding and formulating plans to eradicate biological, psychosocial, economic, and environmental conditions that are detrimental to achieving an optimal quality of life for all individuals.

[1]The Task Force on Ecopsychiatric Data Base included Aristide H. Esser, M.D., acting chairperson, Ronald Chew, M.D., Alfonso Paredes, M.D., Edward Norman, M.D., and Marshall Belaga, M.D., Falk Fellow. (Jay Shurley, M.D., chairperson, was on sabbatical leave at the time this statement was formulated.)

Position Statement on Desegregation of Hospitals for the Mentally Ill and Retarded

This statement, a revision of a statement approved in December 1963, was approved by the Assembly of District Branches at its November 4–5, 1975, meeting and by the Board of Trustees at its December 5–6, 1975, meeting. The revision was recommended by the Council on National Affairs.[1].

THE AMERICAN PSYCHIATRIC ASSOCIATION is in favor of desegregation of all hospitals for the mentally ill and retarded. This statement is offered as contributory to the national will to eliminate legal and social impediments to the extension of all services to all citizens. The acceptance of this principle and its translation into practice would remove the need to duplicate facilities to accommodate segregation. It would release all available resources in support of a wider range of treatment services for the benefit of all mentally ill citizens.

[1]The Council on National Affairs included Harold M. Visotsky, M.D., chairperson, James M. Bell, M.D., vice-chairperson, Hiawatha Harris, M.D., Jean Shioda Bolen, M.D., Frank M. Ochberg, M.D., Hector Jaso, M.D., Assembly of District Branches liaison, Esther P. Roberts, M.D., observer-consultant, and Marshall Belaga, M.D., Ezra Griffith, M.D., and Russell Phillips, M.D., Falk Fellows.

Position Statement on Administration of Psychiatric Facilities

This statement was approved by the Assembly of District Branches at its November 4–5, 1975, meeting and by the Board of Trustees at its December 5–6, 1975, meeting, upon recommendation of the Council on Mental Health Services. It was prepared by the Council on Mental Health Services.[1]

STANDARD 15 of the *Standards for Psychiatric Facilities*, as amended in 1974, is revised by adding the following at the end of the first paragraph at the top of page 11:

> In a psychiatric facility where the chief administrative officer is a non-medical administrator, conflicts which develop between the administrator and the physician regarding the medical-psychiatric management of patients shall be adjudicated by appropriate peer review mechanisms described in the Bylaws of the facility.

It is recognized that there are facilities with an orientation toward prevention of mental illness and disease as well as maintenance of mental health. In such settings, mental health professionals other than psychiatrists may retain the primary responsibility for programs, using psychiatrists for consultation as needed, always taking into consideration the welfare of the patient.

In any psychiatric facility where treatment of mental illness or disease is offered, the physician-psychiatrist shall retain the ultimate responsibility for the admission, diagnosis, treatment, rehabilitation, and discharge of patients under his or her care.

Regular review and evaluation of the mental health programs, policies, and services provided the public should be accomplished by professionals from the disciplines of psychiatry, psychology, social work, nursing, and other qualified mental health professions, with adequate representation from the public consumers of such services. The professionals engaging in such review and evaluation shall have recognized stature in their own professions and have no fiduciary relationship with the system being evaluated.

APA, through existing mechanisms, will provide the drafters of the regulations accompanying Public Law 94-63 with these concepts for inclusion in such regulations.

[1]The Council on Mental Health services included James C. Johnson, M.D., chairperson, Mildred Mitchell-Bateman, M.D., vice-chairperson, Israel Zwerling, M.D., Bruce W. Alspach, M.D., J.M. Stubblebine, M.D., Aubrey Dent, M.D., observer-consultant, and William B. Spriegel, M.D., Assembly of District Branches liaison.

Position Statement on the Training of Minority Psychiatrists

This statement, a revision of a previously approved statement (published in the August 1971 issue), was approved by the Assembly of District Branches at its November 4–5, 1975, meeting and by the Board of Trustees at its December 5–6, 1975, meeting. The revision was recommended by the Council on National Affairs.[1] *The original statement was recommended by the Committee on Medical Education.*[2]

ALL RESIDENCIES must provide treatment facilities; in these facilities the proportion of minority patients should reflect that of the surrounding community and/or represent its ethnic, socioeconomic, and cultural balance.

The future of stipends for psychiatric residents is uncertain, but if they are to be continued, minority residents should be favored. If there are to be loans for psychiatric residents, the lowest possible interest rate should be granted to minority residents, and the interest rate should be lower for those with greater need.

The Assembly of District Branches should study the situation in the district branches to see what effort they are making to deal with minority problems. The Assembly of District Branches may recommend that a specific committee on minority problems be set up within each district branch.

An annotated bibliography of the literature on the treatment of minorities, including papers by both minority and other psychiatrists, should be developed by APA, and the Association should determine how such a bibliography might best be distributed to its membership.

APA must powerfully encourage and support systematic research into such issues as the treatment, demography, sociology, etc., of minorities. These are the same questions that have been studied extensively in whites. The Council on Research and Development should determine if private or public funds are available for such research, because the problem of funding both minority and other research workers is crucial for the future of the Association. While most minority psychiatrists are currently on the "firing line," a few must be protected so that they can do research. This might be done by the National Institute of Mental Health and/or foundations developing career research and teacher funds for minority psychiatrists.

The American Board of Psychiatry and Neurology should investigate residency training programs to see if they are deficient in training minorities. If deficiencies are found, the Residency Review Committee should recommend specific changes, with further certification of the programs dependent upon the implementation of the changes.

The written examination of the Board should include a significant number of questions regarding minority psychiatry, and all oral examiners for the Board should include such questions in their examinations.

An effective residency training program should have an ethnically balanced faculty. Certification should be dependent upon proof of an ethnic balance or upon the presentation of a schedule for the program's achieving such a balance.

It is essential that APA express its sense of urgency in this matter. No unnecessary bureaucratic machinery should slow the process of implementing the recommendations as they are accepted.

[1]The Council on National Affairs included Harold M. Visotsky, M.D., chairperson, James M. Bell, M.D., vice-chairperson, Hiawatha Harris, M.D., Jean Shioda Bolen, M.D., Frank M. Ochberg, M.D., Hector Jaso, M.D., Assembly of District Branches liaison, Esther P. Roberts, M.D., observer-consultant, and Marshall Belaga, M.D., Ezra Griffith, M.D., and Russell Phillips, M.D., Falk Fellows.

[2]The Committee on Medical Education then included Robert J. Stoller, M.D., chairperson, Jeanne Spurlock, M.D., James I. Mathis, M.D., S. Mouchly Small, M.D., Henry Coppolillo, M.D., Manuel Pearson, M.D., and Robin C.A. Hunter, M.D.

The American Board of Psychiatry and Neurology

The following successfully completed the Board examination given in New Orleans, La., Jan. 19–20, 1976.

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication.

TRIAVIL is contraindicated in CNS depression from drugs; in the presence of evidence of bone marrow depression; and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® **containing perphenazine and amitriptyline HCl**

a tranquilizer-antidepressant

for highly effective relief of depression with moderate anxiety

TRIAVIL®

containing perphenazine and amitriptyline HCl a tranquilizer-antidepressant

Available:

TRIAVIL® 2-25: Each tablet contains 2 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 2-10: Each tablet contains 2 mg perphenazine and 10 mg amitriptyline HCl

TRIAVIL® 4-25: Each tablet contains 4 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 4-10: Each tablet contains 4 mg perphenazine and 10 mg amitriptyline HCl

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and that the full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude, muscle weakness, mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

anticoagulants
antacids
cardiac glycosides
diuretics
vasodilators
anticholinergics

Psychotropics/CNS depressants

alcohol
phenothiazines
narcotics
barbiturates
hypnotics
MAO inhibitors
minor tranquilizers
antidepressants

Anticonvulsants

ROCHE

you should know this about Valium® (diazepam)

Valium is frequently used with most classes of these primary medications. Clinically significant drug interactions have not been reported to date.

Potentiation may occur with other CNS depressants. Careful consideration should be given to the pharmacology of these compounds when used concomitantly with Valium.

As with other agents which have anticonvulsant activity, the possibility of increase in frequency and/or severity of grand mal seizures may require an increase in dosage of standard anticonvulsants.

Valium® (diazepam)

2-mg, 5-mg, 10-mg scored tablets Ⓒ IV

Before prescribing, please see following page for a summary of product information

Valium® (diazepam)

2-mg, 5-mg, 10-mg scored tablets

can relieve psychoneurotic anxiety and its associated depressive symptoms

Prompt, effective action. Valium works rapidly to relieve pronounced psychic tension in patients overreacting to stress and in psychoneurotic patients.

Wide margin of safety. Valium is generally well tolerated and in usual dosages rarely produces significant adverse reactions.

Dosage flexibility. Scored Valium 2-, 5-, 10-mg tablets give you dosage flexibility no tranquilizer capsule can match.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10.

Mysoline® (primidone)

may be the start of a better life for the epileptic

initial and maintenance therapy for
grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY
(For full prescribing information, see package circular.)

MYSOLINE® Brand of PRIMIDONE
Anticonvulsant

ACTIONS: MYSOLINE acts on the central nervous system to raise seizure threshold or alter seizure pattern. The mechanism(s) of action of anticonvulsant drugs is not known.

Primidone has anticonvulsant activity *per se*. In addition, its two metabolites possess anticonvulsant qualities. The major metabolite is phenylethylmalonamide (PEMA); the other is phenobarbital. In addition to its own anticonvulsant potential, PEMA potentiates phenobarbital.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several days before it can be assessed.

Use in pregnancy: Recent reports strongly suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Reference has been made to primidone in several cases in which it was used *in combination* with other anticonvulsants; but its teratogenicity has not been conclusively demonstrated. The possibility exists that other factors, *e.g.*, genetic factors or the epileptic condition, may contribute to the higher incidence of birth defects. The data also indicate that the great majority of mothers receiving anticonvulsant medication deliver normal infants.

Anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and risk to both mother and the unborn child.

When the nature, frequency, and severity of the seizures do not pose a clear threat to the patient, good medical practice requires that the physician weigh the expected therapeutic benefit of anticonvulsant therapy against possible risk on an individual basis.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

The physician should weigh all of the foregoing considerations when treating and counseling epileptic women of childbearing potential.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

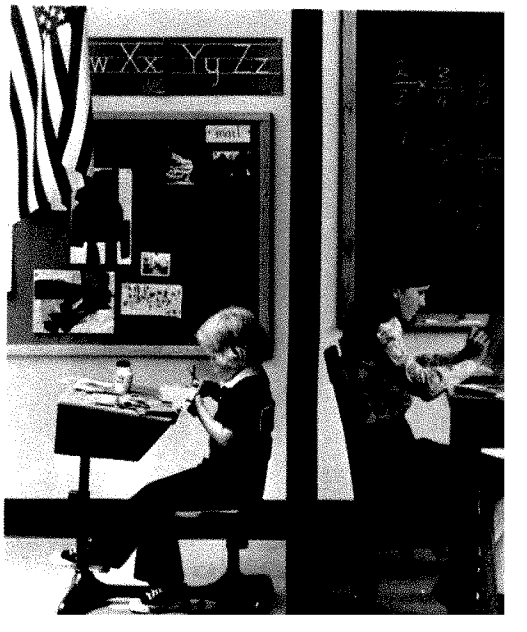
ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 mg. Increments of 250 mg. are added, usually at weekly intervals to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 Gm. A typical dosage schedule for the introduction of MYSOLINE (primidone) is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg., with gradual weekly increases of 125 mg. a day, to a daily total usually between 500 mg. and 750 mg.



In patients already receiving other anticonvulsants, MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances:

- for initiation of combination therapy
- during "transfer" therapy
- for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.)

HOW SUPPLIED: MYSOLINE *Tablets*—No. 430—Each tablet contains 250 mg. of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg. of primidone (scored), in bottles of 100 and 500. MYSOLINE *Suspension*—No. 3850—Each 5 cc. (teaspoonful) contains 250 mg. of primidone, in bottles of 8 fluid-ounces.

Ayerst®
AYERST LABORATORIES
New York, N.Y. 10017

The vulnerable ages

The first epileptic seizure is most likely to occur during early childhood and at the onset of puberty

About 9 out of 10 epileptics experience their first seizure before the age of 20—with the highest incidence between 5 and 7, when children start school, and at the onset of puberty, a time of physiological and psychic turmoil.[1] The most common type, grand mal, occurs in approximately 75% of epileptic children,[1] and more than 50% of patients who suffer initially from petit mal develop grand mal seizures before they reach the age of 16.[2]

Mysoline [primidone] for control of grand mal, psychomotor and focal epilepsy

At the onset and afterwards — used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. *Excellent* for control of grand mal. Valuable for control of psychomotor[1,3,4] and focal epilepsy as well.[5]

Add Mysoline when control with other anticonvulsants is inadequate—As concomitant therapy, MYSOLINE can improve seizure control in grand mal and psychomotor epilepsy. The combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.[6]

Change to Mysoline when other anticonvulsants fail—A changeover to MYSOLINE is frequently warranted when other anticonvulsants must be discontinued because of important side effects, or when grand mal seizures are refractory to phenobarbital, with or without diphenylhydantoin.[7]

New APA Task Force Reports

Behavior Therapy in Psychiatry

This comprehensive report reviews the historical development of behavior therapy, its efficacy for the treatment of psychiatric problems, its current forms and uses as well as potential abuses, and its relationship to dynamic psychiatry. Approved for publication by the APA Council on Research and Development, the Report was prepared by a Task Force comprising Lee Birk, M.D., John Paul Brady, M.D., Alan J. Rosenthal, M.D., W. Douglas Skelton, M.D., Joseph B. Stevens, M.D., and Consultants Stephanie B. Stolz, Ph.D., Joseph V. Brady, Ph.D., Arnold A. Lazarus, Ph.D., James J. Lynch, Ph.D., and Edwin J. Thomas, Ph.D.

Report No. 5 — 75 pages, June 1973 — Single copy $3.50

Patterns of Private Psychiatric Practice

The Present and Future Importance of Patterns of Private Psychiatric Practice in the Delivery of Mental Health Services

This report marks the first formal statement the Association has ever issued delineating the vital role of its private practitioner members in the delivery of mental health services in the U.S. Contains sections on patterns of private practice, the economics of it, the impact of third party payments on it, its relation to the public sector, and an assessment of the overall contribution of the private sector to the treatment of mental illness. Stresses the theme that any national system for the delivery of mental health services must be a "balanced mix" of both the private and public sectors, each reinforcing the other. Approved for publication by the Council on Mental Health Services, the Report was prepared by a Task Force comprising Drs. Ewald Busse, Rogers J. Smith, Reed S. Andrus, Winston Cochran, Albert A. Lorenz, Robert L. Leopold, Louis W. Nie, and Consultants Alan I. Levenson, Zigmond M. Lebensohn, Walter E. Barton, and Mr. Robert L. Robinson.

Report No. 6 — 29 pages, June 1973 — Single copy $2.00

Megavitamin and Orthomolecular Therapy in Psychiatry

This comprehensive report reviews and evaluates claims for the effectiveness of the megavitamin rationale, clinical trials of NA and NAA with criticisms and attempts at replication, early clinical trials and attempts at replication, pellagra, schizophrenia and the question of NAD, the diagnosis of schizophrenia, patient selection, and specific phase-treatment programs of orthomolecular psychiatrists, quantitative aspects of megavitamin therapy, incompatibility of Methyl-receptor and NAD positions, and toxicity. Published with the approval of the Council on Research and Development, the Report was prepared by a Task Force comprising Drs. Morris Lipton, Thomas A. Ban, Francis J. Kane, Jerome Levine, and Consultant Richard Wittenborn, Ph.D.

Report No. 7 — 54 pages, June 1973 — Single copy $3.00

McNeil Laboratories, Inc., 1976

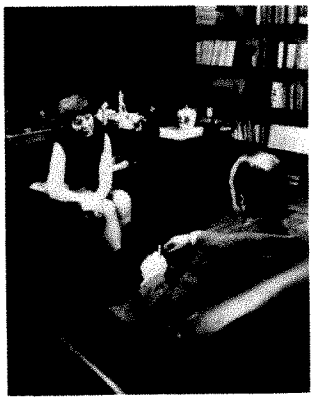
Haldol®
(haloperidol)
tablets/concentrate/injection

For prompt control with minimal risk of hypotension or oversedation

Highly effective in a wide range of psychotic symptoms[1-7]
such as hallucinations, delusions, suspiciousness, hostility, mania, psychomotor agitation, etc., in both acute and chronic disorders.

Helps keep patients functioning and avoid hospitalization.[1-3]
HALDOL haloperidol usually leaves most patients alert and responsive, able to function at work and at home without impairment, and more amenable to other therapeutic measures.

Permits aggressive titration to effective dosage levels[1,4]
up to 100 mg/day orally (with minimal risk of usual troublesome reactions) to achieve optimal response when patient is inadequately controlled at lower dosage...to help you rapidly control and stabilize new patients, promptly regain control during periods of exacerbation.



Common side effects easily controlled.[1,2,4]
Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Reduces risk of certain troublesome reactions.[1,2,4-6]
Transient hypotension occurs rarely and severe orthostatic hypotension has not been reported. Marked sedation is rare, although some instances of drowsiness have been reported. In addition, with chronic use, it is unlikely to cause hepatic damage, serious hematologic reactions, photosensitivity reactions and skin rashes...and has minimal effect on renal function.

Please turn page for information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions.

Important: Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

Haldol® (haloperidol)

tablets/concentrate/injection

For prompt control of psychotic symptoms with minimal risk of hypotension or oversedation

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

A tasteless, odorless, colorless liquid concentrate for better patient acceptability: 2 mg. per ml.

A rapid-acting injection for psychiatric emergencies: 5 mg. per ml., with 1.8 mg. methylparaben and 0.2 mg. propylparaben per ml., and lactic acid for pH adjustment to 3.4±0.2.

Indications: HALDOL haloperidol is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's syndrome.

Contraindications: HALDOL haloperidol is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL haloperidol in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of haloperidol orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL haloperidol, decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL haloperidol may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL haloperidol should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL haloperidol may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant antiparkinson medication is required, it may have to be continued after HALDOL haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson agents, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of antiparkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long-term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed. 9/74

In clinically significant depression

TABLETS, 5 mg and 10 mg

Vivactil®*

(Protriptyline HCl|MSD)

*** When you want an antidepressant that is characteristically nonsedating for the patient under close medical supervision (Symptoms such as anxiety or agitation may be aggravated.)**

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information please see following page.

In clinically significant depression

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD)

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. May enhance response to alcohol and effects of barbiturates and other CNS depressants. Possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent administration with electroshock therapy may increase hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue drug several days before elective surgery, if possible. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of other tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

For more detailed information, consult your MSD representative or see full prescribing information.

PSYCHIATRISTS

Full-Time Director for the Psychosomatic-Psychiatric Liaison Service in the University of California School of Medicine, San Francisco. Will be responsible for consultative services, training of medical students, interns, residents in emotional factors of illness, postgraduate education for staff and community physicians. Will hold faculty title of Associate Professor or Professor of Psychiatry. Need administrative skills in coordinating all existing relationships between psychiatry and other clinical services, establishing training, service and research where such activities would be appropriate and do not yet exist. Qualified candidates representing minorities and women encouraged to apply.

Direct inquiries to:
Ms. Mary Asahina, Dept. Admin. Assist.
Langley Porter Neuropsychiatric Inst.
401 Parnassus Avenue
San Francisco, CA 94143

PSYCHIATRIC IN-PATIENT SERVICES HEAD

University Hospital, Indiana University School of Medicine; Indiana licensed M.D. with residency training in Psychiatry and prior academic experience in a related basic Psychiatric science and evidence of research. Salary range $22,500-$28,000 as Associate Professor of Indiana University School of Medicine with many fringe benefits including TIAA policy paid by the University; 12 month year. Teaching duties include supervision of residents of Psychiatry, medical students and other professional groups retained through the In-patient Department; in addition to responsibility for procedures, medical records, referrals, etc. for the over-all management of the Psychiatric in-patient service involving individual patient care. Qualified and interested individuals may send Vita to Dr. Hugh C. Hendrie, Chairman, Department of Psychiatry, University Hospital, 6 North, Indiana University School of Medicine, Indianapolis, Indiana 46202.

AN EQUAL OPPORTUNITY EMPLOYER
AN AFFIRMATIVE ACTION POLICY

Three Treatment Centers

Three treatment centers provide individually prescribed programs of care, education, treatment and training for children, adolescents and adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.

Advantage: the availability of a **large, trained and experienced staff,** exchanging ideas and insights in a comprehensive program of supportive environment and individualized treatment.

Advantage: **geographically separated** to provide the proper residential milieu . . . yet near enough to benefit from the combined training and experience of a wide range of staff members.

The Oaks — A residential psychiatric treatment center for emotionally disturbed children and adolescents between the ages of six and 18. Co-educational, Austin. In addition, the Center provides a Short Term Adolescent Center and a six bed intensive care unit.

The San Marcos Treatment Center — a facility with three campuses designed for individuals with psychiatric, neurological, and intellectual difficulties who have evidenced a need for a 24-hour therapeutic milieu.

The Center offers a broad spectrum of services to both mentally retarded individuals and those with psychiatric disorders. In addition to a structured therapeutic environment, individual and group psychotherapy services are available to each resident. Clinical supervision and support services are provided by the Center psychiatrists.

The Ranch Treatment Center — located in the suburbs of Austin the Center provides both long-term and intermediate tenure services to multi-handicapped male adolescents and adults whose primary diagnostic classifications are in areas of mental retardation and mental illness. All residents receive program services which may permit their early discharge to the less restrictive settings of community-based programs.

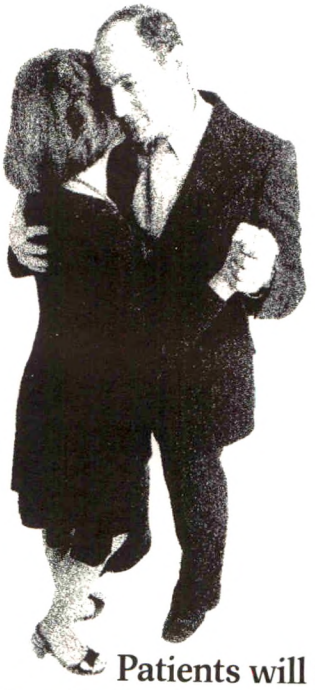
ROCHE

Introducing

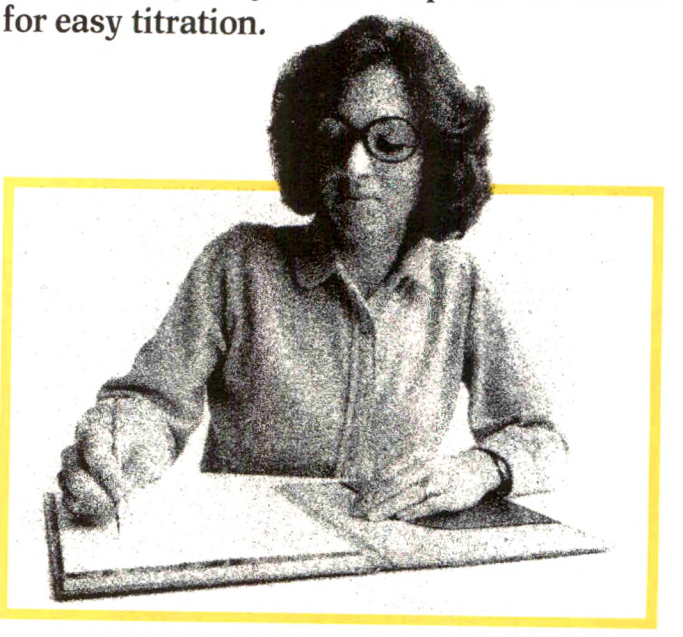
The unforgettable antidepressant

Endep™ 75 mg

amitriptyline HCl / Roche



Here's what makes it unforgettable



Patients are more likely to remember the single bedtime dosage of Endep (amitriptyline HCl).

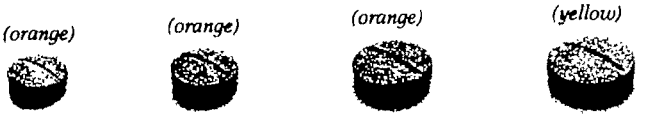
You'll remember 1 or 2 tablets *h.s.*, because fewer forgotten doses produce a more consistent clinical effect, and because it is the only tricyclic antidepressant scored for easy titration.

Patients will also remember family/interpersonal relationships that they have forgotten or neglected.

In three or four weeks patients will usually remember how well they used to feel.

Endep™ 75 mg

amitriptyline HCl/Roche



The antidepressant you can prescribe at night to work all day

Before prescribing, please consult complete product information, a summary of which appears on the following page.

Introducing Endep™

amitriptyline HCl/Roche

The antidepressant you can prescribe at night to work all day

10-mg scored tablets | **25-mg** scored tablets | **50-mg** scored tablets | **75-mg** scored tablets

■ Endep (amitriptyline HCl), in responsive patients, lifts mood and relieves symptoms such as anorexia, loss of interest, inability to concentrate, decreased libido or GI disturbances, often within three or four weeks after starting therapy.

■ Endep usually relieves accompanying sleep disturbances, particularly early in the treatment regimen.

■ All four dosage strengths are scored for greater flexibility and convenience in titration.

■ The 75-mg *h.s.* dose minimizes skipped doses, maximizes patient acceptance and compliance.

■ Specifying Endep/Roche assures quality plus potential economy.

Important Considerations

Should not be given concomitantly with an MAO inhibitor.

Not recommended for use during the acute recovery phase following myocardial infarction.

Contraindicated in patients with hypersensitivity to amitriptyline.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: To relieve symptoms of depression (notably endogenous depression) and depression accompanied by anxiety.

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh potential benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia. purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Dosage: Initiate at low levels; increase gradually, watching for signs of intolerance. As long as 30 days may elapse before adequate antidepressant effect develops; sedative effect may be noted earlier. *Initial Adult Dosage:* Outpatients—25 mg t.i.d.; may be increased to 150 mg/day. Add increased drug to afternoon and/or bedtime doses. Alternate—50 to 100 mg h.s., gradually increasing h.s. dose up to 150 mg/day. Hospitalized Patients—Up to 100 mg/day; increase gradually to 200 mg if necessary. A few patients may require 300 mg/day. *Adolescent and Elderly Patients:* In general, 10 mg t.i.d. with 20 mg h.s. may be satisfactory for those who do not tolerate higher doses. *Maintenance Dosage:* With symptomatic improvement, reduce dosage to lowest amount that gives relief, usually 25 mg b.i.d. to q.i.d., or 10 mg q.i.d. Continue maintenance therapy 3 months or longer to avoid relapse.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. IV administration of 1 to 3 mg physostigmine salicylate reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestations and treatment.

Supplied: 10-mg, 25-mg, 50-mg and 75-mg scored tablets—bottles of 100 and 500; Prescription Paks of 60 (10 mg, 25 mg and 50 mg) or 30 (75 mg), available singly and in trays of 10.

Goodenough-Harris Draw-a-Person test from a study in which Cylert was included in the treatment program

Drawing made prior to treatment

Drawing made at week 8 during treatment

Cylert (pemoline) will not in itself "enhance learning" or resolve difficult behavioral problems. But it can increase attention span in the hyperkinetic child and reduce the impulsivity that often interferes with the learning process.

Cylert® (pemoline)

offers these benefits in a treatment program for MBD

- **Single daily dose administration**
- **Minimal cardiovascular effects**
- **Mean dosage in long-term studies remained remarkably constant**

EFFICACY

Multi-clinic study[1,2]

21 investigators from 10 states and two provinces in Canada took part in the clinical studies.

Double-blind, placebo control

413 patients were randomly assigned to Cylert or placebo groups. 238 patients met all criteria for evaluation of efficacy.

Psychological test results

Children on Cylert had significantly higher scores statistically than those on placebo on these psychological tests:

- The Wechsler Intelligence Scale for Children (WISC) and its performance IQ Sub-Component
- The Wide Range Achievement Test (WRAT) (reading and arithmetic)
- The Lincoln-Oseretsky Motor Performance Test Factor II

Overall results

Approximately two out of three patients were significantly improved by treatment with Cylert as reflected by global ratings.

1. Conners, C. K., ed., *Clinical Use of Stimulant Drugs in Children,* Excerpta Medica, 1974, p. 98.
2. Page, J. G., et al., J. Learning Disabilities, 7:498, Oct., 1974.

SAFETY

Multi-clinic study (9 weeks); safety data analyzed on 407 patients

There was no significant difference between Cylert and placebo groups in:

- Blood pressure
- Laboratory tests
- Pulse
- Neurological status

Insomnia and anorexia were the most frequently seen side effects and often improved with continuation of treatment or reduction of dosage.

Mean weight loss of 1.1 lbs. was demonstrated in the Cylert group during early weeks of treatment; long-term studies have shown that by 3-6 months, most children return to the normal rate of weight gain for their age group.

Long-term study on Cylert; up to 3 years and continuing

Mean dosage . . . remained remarkably constant.
Blood pressure . . no significant changes attributed to Cylert.
Pulse rate . . . . . no significant changes attributed to Cylert.

Laboratory examination—mild to moderate increase in transaminase (SGOT and SGPT) levels in 1-2% of patients (no clinical symptoms); levels returned to normal on withdrawal of medication.

No clinically significant abnormalities in the other tests.

Please see last page of this advertisement for Prescribing Information.

Importance of single daily dosage to the child, the parents and the teacher

For the child		For the adults
No drug in child's possession while at school	⟷	Control of medication remains with parents
Avoids situation in which child is repeatedly singled out as being "different"	⟷	Obviates need for nurse or teacher to supervise taking of mid-day doses
Helps prevent possible variations in effect caused by missed, forgotten or delayed doses	⟷	Helps assure that the prescribed dosage is being given each day

Cylert (pemoline), alone among CNS stimulants used to treat MBD, is inherently long-acting, permitting once-daily dosage.

Cylert can be taken with meals

You can prescribe Cylert a.c., p.c., or with meals. Although the speed of absorption is slightly slowed by food, the total absorption is not affected.

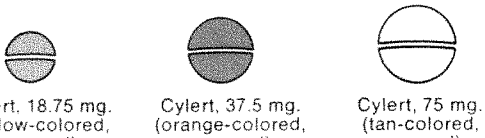
Dosage and administration

Cylert is given as a single oral dose each morning.

The recommended starting dose is 37.5 mg. per day. This daily dosage should be gradually increased at one-week intervals using increments of 18.75 mg. until the desired clinical response is obtained.

The mean daily effective dose ranges from 56.25 to 75 mg. per day. The maximum recommended daily dose of Cylert is 112.5 mg.

Using the recommended schedule of dose titration, significant benefits may not be seen until the third or fourth week of drug therapy. Side effects may be seen prior to optimum clinical results.



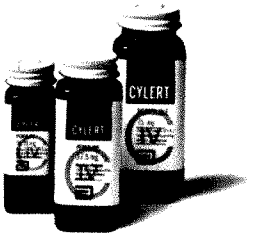
When not to use Cylert

Cylert should not be used for (and will not be effective in) simple cases of overactivity in school-age children.

Neither should it be used in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

The physician should rely on a complete history of the child and a thorough description of symptoms from both parents and teacher before postulating a diagnosis of MBD.

The three dosage strengths of Cylert (pemoline)



Cylert, 18.75 mg. (yellow-colored, grooved)

Cylert, 37.5 mg. (orange-colored, grooved)

Cylert, 75 mg. (tan-colored, grooved)

Tablets are actual size.

Cylert
(pemoline) C IV

Prescribing Information

Description: Cylert (pemoline) is a white, tasteless, odorless powder which is relatively insoluble (less than 1 mg/ml) in water, chloroform, ether, acetone, and benzene. In 95% ethyl alcohol, the solubility of pemoline is 2.2 mg/ml.

Actions: Cylert (pemoline) is a central nervous system stimulant. The pharmacologic activity of pemoline is similar to that of other known stimulants but with minimal sympathomimetic effects. Pemoline is structurally dissimilar from the amphetamines and methylphenidate. Although the exact mode of pharmacodynamic action is undetermined in man, pemoline has been reported to increase the rate of synthesis of dopamine in rat brain.

In human subjects, Cylert produces peak blood levels within 2-4 hours. The serum half-life is approximately 12 hours. Multiple dose studies in adults at several dose levels indicate that serum levels plateau in approximately three days. Cylert and its metabolites are primarily excreted by the kidneys with approximately 75% of an oral dose appearing in the urine within a 24-hour period. Approximately 43% of pemoline is excreted unchanged. Metabolites include pemoline dione, conjugated pemoline and mandelic acid.

Cylert (pemoline) has a gradual onset of action in children with minimal brain dysfunction. Using the recommended schedule of dosage titration, significant clinical benefit may not be evident until the third or fourth week of drug administration.

Indications: MINIMAL BRAIN DYSFUNCTION IN CHILDREN—as adjunctive therapy to other remedial measures (psychological, educational, social).

Special Diagnostic Considerations: Specific etiology of minimal brain dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis includes the use not only of medical but of psychological, educational, and social resources.

Characteristics commonly reported include: A chronic history of moderate to severe hyperactivity, short attention span, distractibility, emotional lability, and impulsivity. Nonlocalizing (soft) neurological signs, learning disability, and abnormal EEG may or may not be present. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. In the primary therapy of MBD, appropriate educational placement is essential and psychosocial intervention is generally necessary. When these measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis.

Contraindication: Cylert (pemoline) is contraindicated in patients with known hypersensitivity or idiosyncrasy to the drug. (See PRECAUTIONS)

Warnings: Cylert is not recommended for children under six years of age since safety and efficacy in this age group have not yet been established.

Since Cylert (pemoline) and its metabolites are excreted primarily by the kidneys, caution should be observed in administering the drug to children with significantly impaired renal function.

Sufficient data on safety and efficacy of Cylert administration for periods beyond two years duration in children with minimal brain dysfunction are not yet available. Although a definite causal relationship has not been established, some temporary suppression of predicted growth pattern(i.e., weight and/or height) has been reported with the long-term use of stimulants in children. Therefore, patients requiring long-term therapy should be carefully monitored.

Drug Interactions: Interactions between Cylert and other drugs have not been studied in humans. As with most other drugs, concurrent administration with other agents, especially drugs with central nervous system activity, should be carefully monitored.

Usage in Pregnancy: Safety for use in pregnancy has not been established. Standard studies of fertility, teratology and reproduction were conducted in rats and rabbits. Daily oral doses of pemoline of 18.75 and 37.5 mg/kg beginning at conception produced no abnormalities in the fetuses and did not affect viability at birth. Further studies using similar dose levels with drug administration beginning 14 days before conception demonstrated an increased incidence of stillbirths in these animals.

Drug Dependence: Studies of the drug abuse potential of Cylert (pemoline) in primates have not demonstrated a potential for self-administration. However, the pharmacologic similarities between Cylert and other CNS stimulants with known abuse liability suggest that drug dependence of the stimulant type might occur. There have been isolated reports of transient psychotic symptoms in adults following long-term misuse of pemoline taken orally in excessive quantities. Therefore, caution should be observed in emotionally unstable patients considered to have a psychological potential for drug dependence.

Precautions: Delayed hypersensitivity reactions involving the liver have been reported in 1-2% of the patients receiving Cylert usually after several months of therapy. No clinical symptomatology has been observed, but mild to moderate increases in transaminase (SGOT and SGPT) levels have occurred in these cases. These effects appear to be completely reversible when drug treatment is discontinued. Transaminase levels should be determined periodically during therapy with Cylert to detect any such reactions.

Adverse Reactions: The most frequently reported adverse reaction with Cylert is insomnia. Insomnia has been observed prior to optimum therapeutic response and in the majority of cases was transient in nature or responded to dosage reduction. Anorexia with weight loss during the first few weeks of therapy has also been reported. With continuing therapy, a return to a normal weight curve usually occurred within three to six months. Other adverse reactions reported include stomachache, skin rash, irritability, mild depression, nausea, dizziness, headache, drowsiness, and hallucinations. Mild adverse reactions appearing early in treatment often remit with continuing therapy. If adverse reactions are of a significant or protracted nature, dosage reduction or discontinuation should be considered.

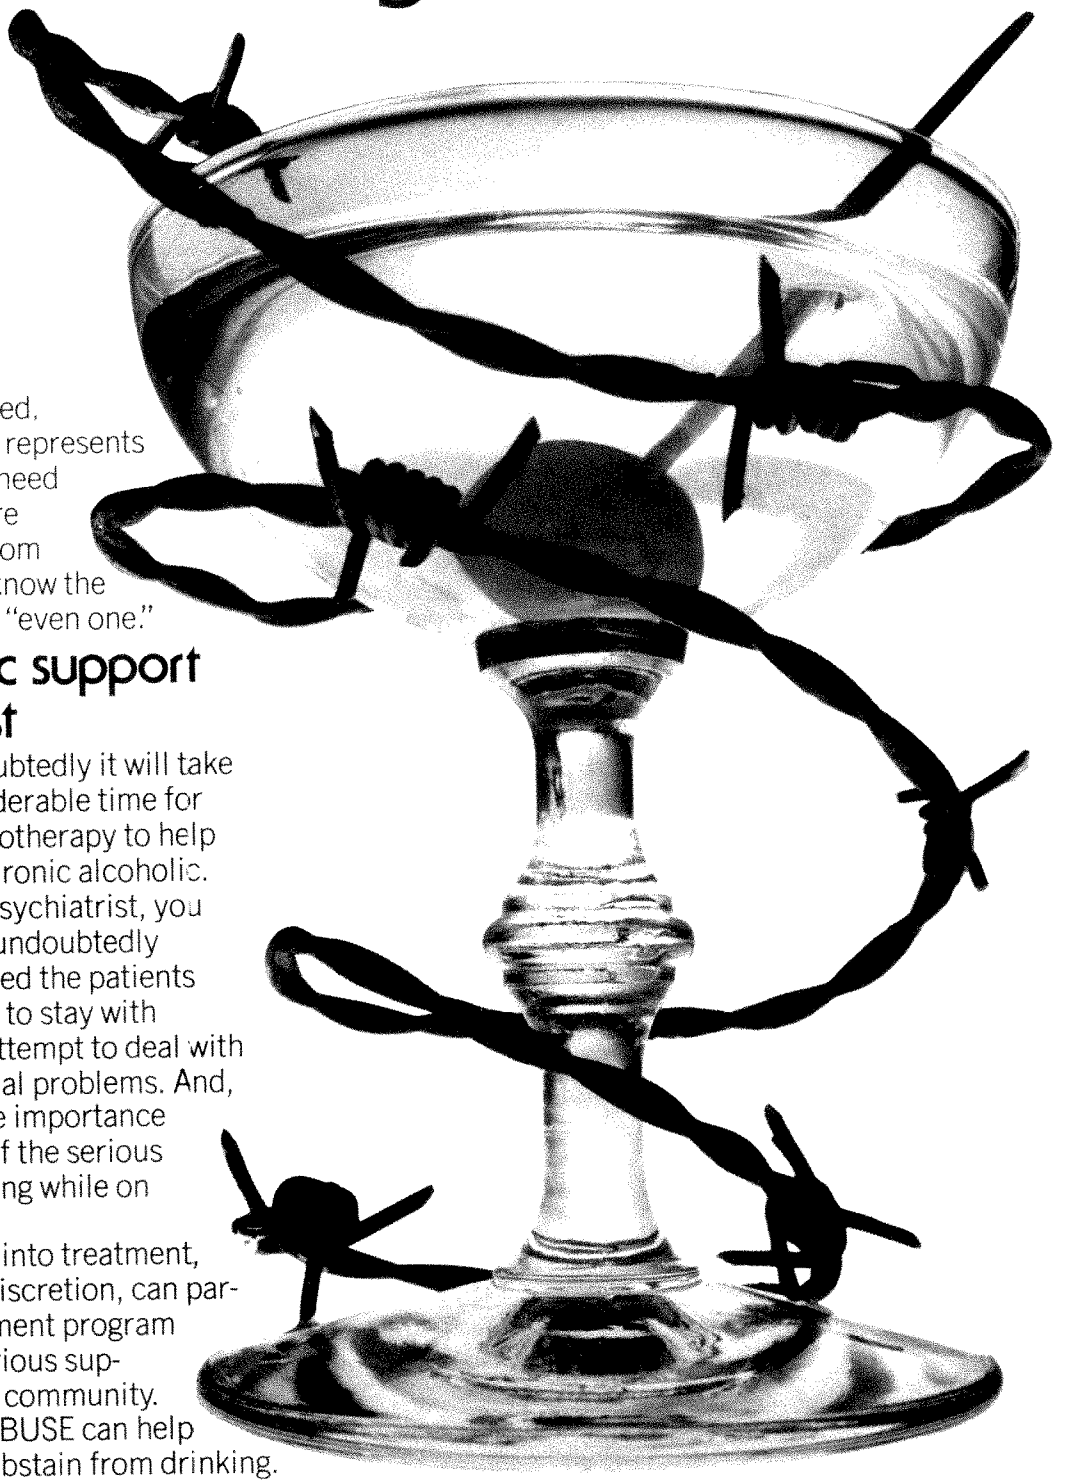
Dosage and Administration: Cylert (pemoline) is administered as a single oral dose each morning. The recommended starting dose is 37.5 mg per day. This daily dosage should be gradually increased at one week intervals using increments of 18.75 mg until the desired clinical response is obtained. The mean daily effective dose ranges from 56.25 to 75 mg per day. The maximum recommended daily dose of pemoline is 112.5 mg.

Clinical improvement with Cylert is gradual. Using the recommended schedule of dosage titration, significant benefit may not be evident until the third or fourth week of drug administration. Drug administration should be interrupted occasionally to determine if behavioral symptoms sufficient to require continuing therapy recur.

Overdosage: Cylert overdosage has been reported to produce symptoms of tachycardia, hallucinations, agitation, or restlessness. The treatment of acute massive overdosage with pemoline is essentially the same as that for overdosage with any drug having CNS stimulatory effects. Management is largely symptomatic and may include induction of emesis, gastric lavage or other measures as appropriate.

How Supplied: Cylert (pemoline) is supplied as monogrammed, grooved tablets in three dosage strengths:

18.75 mg. tablets (yellow-colored) in bottles of 100 (**NDC** 0074-6025-13)



37.5 mg. tablets (orange-colored) in bottles of 100 (**NDC** 0074-6057-13)

75 mg. tablets (tan-colored) in bottles of 100 (**NDC** 0074-6073-13)

ABBOTT LABORATORIES
North Chicago, IL60064

ANTABUSE: "Social security" for the alcoholic who wants to stop drinking...

The temptation is resisted. ANTABUSE (disulfiram) represents the security alcoholics need in any situation. They are better able to abstain from drinking because they know the consequences of taking "even one."

until psychiatric support can do the rest

Undoubtedly it will take considerable time for psychotherapy to help the chronic alcoholic. As a psychiatrist, you have undoubtedly selected the patients who are best motivated to stay with ANTABUSE while you attempt to deal with the underlying emotional problems. And, of course, you know the importance of reminding patients of the serious consequences of drinking while on ANTABUSE.

Once sober, and well into treatment, the alcoholic, at your discretion, can participate in a total treatment program which makes use of various supportive resources in the community. In the meantime, ANTABUSE can help the chronic alcoholic abstain from drinking.

BRIEF SUMMARY
(For full prescribing information, see package circular.)

ANTABUSE® (disulfiram) in Alcoholism

INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)

CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, e.g. cough syrups, tonics, and the like, should not be given ANTABUSE.

ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.

WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.

The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.

THE ANTABUSE-ALCOHOL REACTION: ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.

The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.

The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.

DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.

Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.

It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.

Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.

CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.

USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE (disulfiram) should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.

PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)

Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.

Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)

Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.

In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.

Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.

There have been reports of polyneuritis and peripheral neuritis, and rare instances of optic neuritis. One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.

DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.

INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.

MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.

NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE (disulfiram), report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.

DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.

TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.

However, where a test reaction is deemed necessary, the suggested procedure is as follows:

After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (½ oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.

MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.

HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100. No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000.

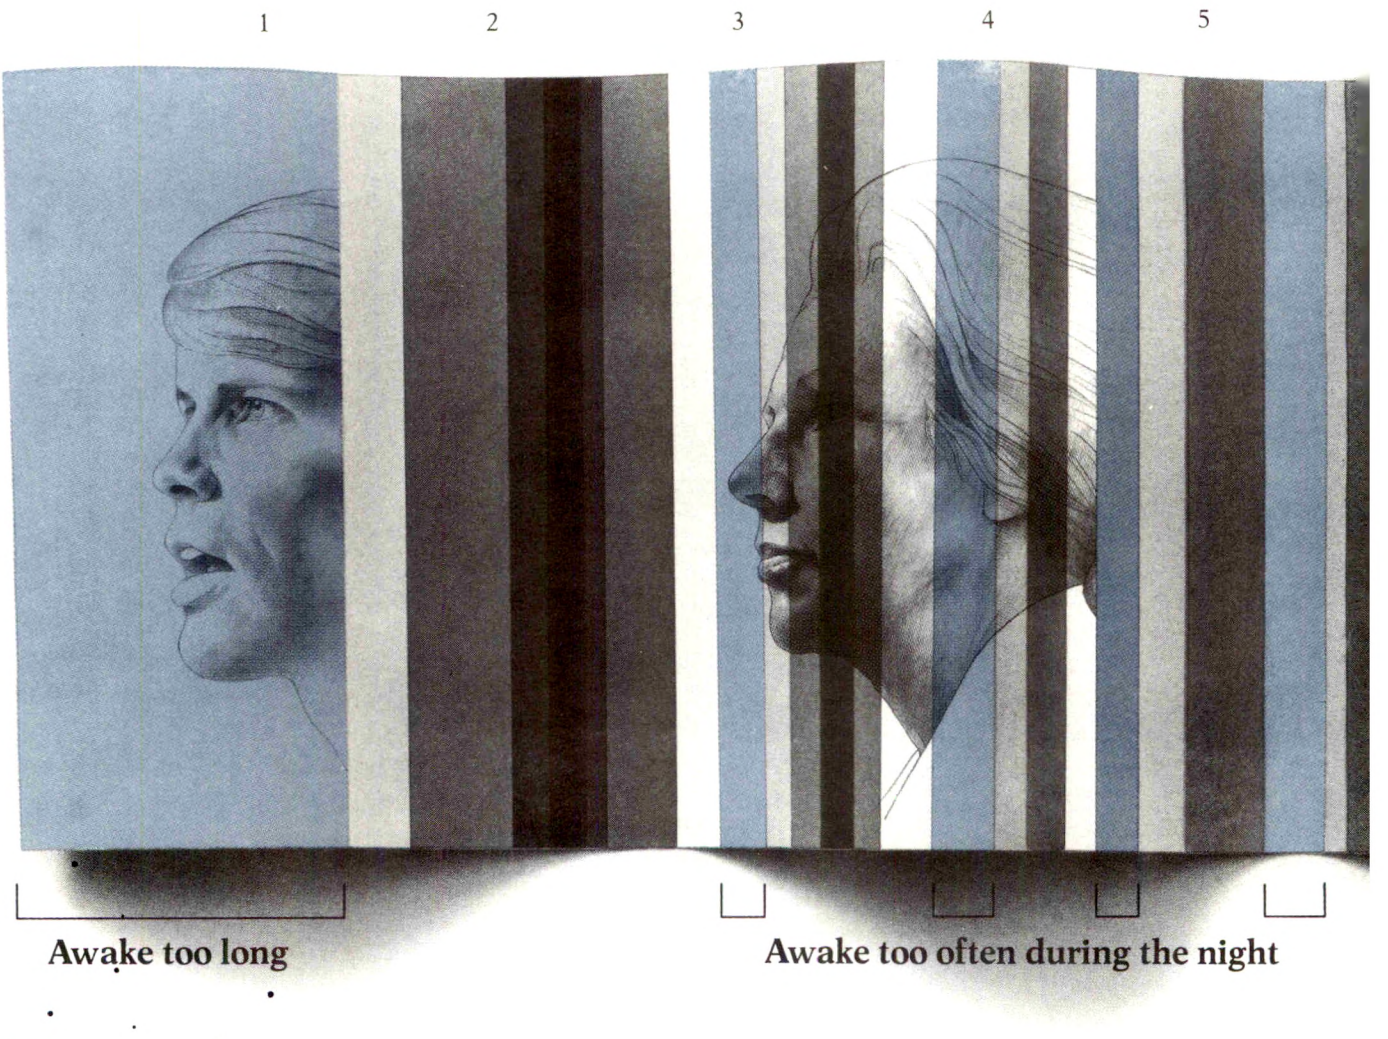
ANTABUSE®

BRAND OF DISULFIRAM

Effectiveness across the spectrum of most common forms of insomnia



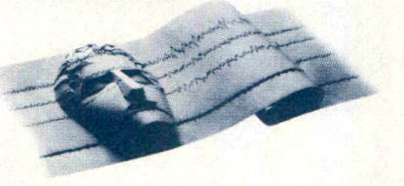
Awake too long, awake too often, awake too early...

These are the most common forms of insomnia, and may occur singly or in any combination. The night of troubled sleep depicted here comprises all three types. As the night progresses from left to right, each sleep stage is identifiable by its own shade of gray. Blue represents "Awake."

As you can see, this hypothetical "patient" takes well over an hour to fall asleep, awakens several times during the middle of the night and awakens too early in the morning.

Sleep Stages

- Awake
- REM
- Stage 1
- Stage 2
- Stage 3
- Stage 4



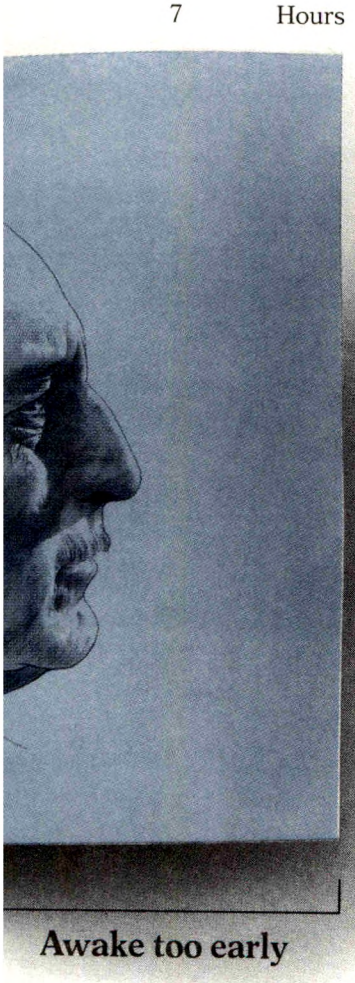
The insomnias most often occurring in young and older adults

For patients with trouble falling asleep (common in young adult insomnia patients), Dalmane (flurazepam HCl) 30 mg provides sleep within 17 minutes, on average. For those with trouble staying asleep or sleeping long enough (common in those over 50), Dalmane offers increased total sleep time with fewer nocturnal awakenings. These clinical results were demonstrated in studies conducted in four geographically separated sleep research laboratories.[1-4]

The relative safety of Dalmane (flurazepam HCl) is well documented

Dalmane (flurazepam HCl) is relatively safe and well tolerated; morning "hang-over" has been infrequent. The usual adult dosage is 30 mg; in elderly or debilitated patients, limit initial dosage to 15 mg to preclude over-sedation, dizziness or ataxia. Caution patients about possible combined effects with alcohol and other CNS depressants.

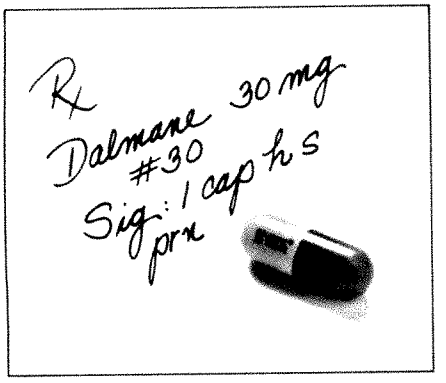
Broad-spectrum medication for the most common forms of insomnia



Dalmane®
(flurazepam HCl)

One 30-mg capsule *h.s.*— usual adult dosage
(15 mg may suffice in some patients).
One 15-mg capsule *h.s.*— initial dosage for elderly or debilitated patients.

- □ induces sleep rapidly
- □ reduces nighttime awakenings
- □ lengthens total sleep time



ROCHE

Please see following page for a summary of complete product information.

Broad-spectrum medication for the most common forms of insomnia

Dalmane®
(flurazepam HCl) ℞ IV

Objectively proved in the sleep research laboratory, Dalmane

- induces sleep within 17 minutes, on average
- reduces nighttime awakenings
- provides 7 to 8 hours sleep, on average, without repeating dosage

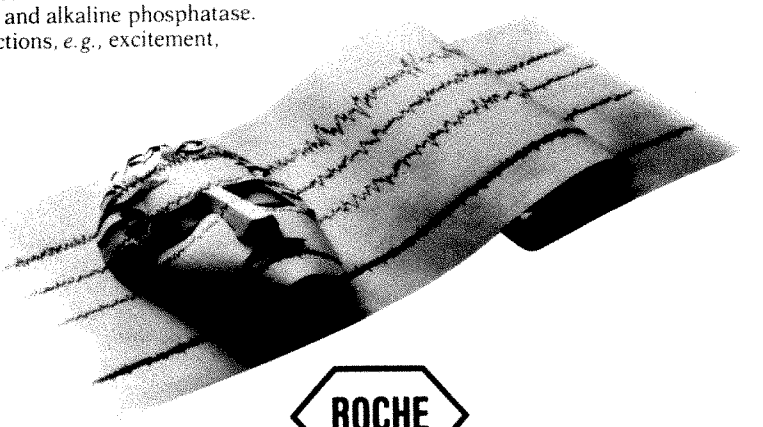
Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, initial dosage should be limited to 15 mg to preclude oversedation dizziness and/or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.



Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

Basic tool of Western psychiatry

Thorazine®
(chlorpromazine, SK&F)

Tablets: 25 and 50 mg of the HCl

- 'Thorazine' controls psychotic symptoms
- Especially useful in agitated, violent or anxious schizophrenic patients
- Unsurpassed clinical experience
- 18 convenient dosage forms and strengths

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.
NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.; Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

For effective management of schizophrenic symptoms.

Coverage and Utilization of Care for Mental Conditions Under Health Insurance —Various Studies, 1973–74

By Louis S. Reed, Ph.D.
Consultant in Health Economics, American Psychiatric Association

This book reports six studies that add to the growing body of data demonstrating the feasibility of covering mental illness under health insurance. Although in some ways it may be considered a supplement to APA's 1972 book **HEALTH INSURANCE AND PSYCHIATRIC CARE: UTILIZATION AND COST** (Reed, Myers, and Scheidemandel), all of the data are new. The studies cover the following areas:

- Utilization of mental benefits under the Blue Cross and Blue Shield plan for federal employees, documenting that a "plateau" in the use of these benefits was reached in 1973–74.
- Comparison of benefits for mental and other illnesses under selected employee health benefit plans.
- Coverage of mental illness under collective bargaining agreements of selected unions.
- Utilization of care for mental conditions under the Canadian health insurance program, which gives the same coverage for mental as for other conditions.
- Updating of information on Blue Cross benefits for hospital care of mental illness.
- Data from selected Blue Cross and Blue Shield plans on coverage and utilization of mental conditions, with emphasis on major medical coverage.

AMERICAN PSYCHIATRIC ASSOCIATION

The American Journal of Psychiatry, formerly *The American Journal of Insanity*, is published monthly by the American Psychiatric Association. Editorial office: 1700 Eighteenth Street, N.W., Washington, D.C. 20009; telephone (202) 232-7878.

Subscriptions: U.S. $18.00 per year, Canada and South America $19.00, other foreign $22.00; single issues: $2.25 plus postage.

Business communications and changes of address from APA members should be directed to the Division of Membership Services and Studies. Communications from non-member subscribers should be directed to the Circulation Department, American Psychiatric Association, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Four to six weeks advance notice is required for changes of address.

Advertising representatives: Steven K. Herlitz, Inc., 850 Third Avenue, New York, N.Y. 10022.

Type set by Bru-El Graphic, Inc., 5408 Port Royal Road, Springfield, Va. 22151.

Printed by Dartmouth Printing Co., 69 Lyme Road, Hanover, N.H. 03755.

Second class postage paid at Washington, D.C., and additional mailing offices.

Indexed in *Abstracts for Social Workers, Biological Abstracts, Chemical Abstracts, Cumulative Index to Nursing Literature, Excerpta Medica, Hospital Literature Index, Index Medicus, International Nursing Index, Nutrition Abstracts, Psychological Abstracts, and Social Sciences Index.*

THE AMERICAN JOURNAL OF PSYCHIATRY

CONTENTS Vol. 133, No. 6 June 1976

609 The Syndrome of Autism: A Critical Review
Edward M. Ornitz and Edward R. Ritvo

622 EEG Sleep Changes as Predictors in Depression
David J. Kupfer, F. Gordon Foster, Louis Reich, Kenneth S. Thompson, and Brian Weiss

627 Cocaine, Kindling, and Psychosis
Robert M. Post and Richard T. Kopanda

635 The "Intoxication State of Consciousness": A Model for Alcohol and Drug Abuse
Marc Galanter

641 The Future of Alcohology: Craft or Science?
Melvyn Kalb and Morton S. Propper

646 Clinical Response and Plasma Levels: Effect of Dose, Dosage Schedules, and Drug Interactions on Plasma Chlorpromazine Levels
Leonor Rivera-Calimlim, Henry Nasrallah, John Strauss, and Louis Lasagna

653 Can Psychiatry Police Itself Effectively? The Experience of One District Branch
Arthur Zitrin and Henriette Klein

657 Cultural Perspectives on the Impact of Women's Changing Roles on Psychiatry
Virginia Abernethy

662 The Behavior of Hypersexual Delinquent Girls
Jerome D. Goodman

TOPICAL PAPERS: The Family

669 A General Systems Approach to Severe Family Pathology
Stephen Fleck

674 The Fatal Myth of Death in the Family
E. Mansell Pattison

679 A New Concept and Finding in Morbid Jealousy
John P. Docherty and Jean Ellis

683 Treatment for the Parents of Feminine Boys
Lawrence E. Newman

BRIEF COMMUNICATIONS

688 ECT in the Treatment of Mania: A Controlled Study
Michael S. McCabe

691 Psychiatric Illness in Homicide Victims
Marijan Herjanic and David A. Meyer

694 Forensic Psychiatry: Profiles of Two Types of Sex Offenders
Fritz A. Henn, Marijan Herjanic, and Robert H. Vanderpearl

697 Peer Review of Prescribing Patterns in a CMHC
Herbert Diamond, Richard Tislow, Thoburn Snyder, Jr., and Karl Rickels

700 Use of the Problem-Oriented Medical Record in Psychiatry: A Survey of University-Based Residency Training Programs
Edward H. Liston

703 Low Urinary Dopamine and Prediction of Phenothiazine-Induced Parkinsonism: A Preliminary Report
Thomas J. Crowley, Charles O. Rutledge, Margaret M. Hoehn, Mary Ann Stallings, and Seymour Sundell

706 Sex Bias in Psychotherapy: A Failure to Confirm
Stephen I. Abramowitz, Howard B. Roback, Joseph M. Schwartz, Amy Yasuna, Christine V. Abramowitz, and Beverly Gomes

710 Anticipating the Impact of Public Law 93-641 on Mental Health Services
Arnold Milstein

713 LETTERS TO THE EDITOR

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone (202-232-7878), should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; in the case of other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Wash., D.C. 20009; there will usually be a charge for granting this permission.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals to aid in comprehension and to break the typographical monotony of lengthy texts. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed eight typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the co-author who has been designated to handle the galley proofs and reprint requests. The number of authors should preferably not exceed four, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it, in which case the author may make any necessary changes on the galley proofs.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Titles and headings of any tables and figures should be sufficiently clear that the meaning of the data is understandable without reference to the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the manuscript. Most figures will be reduced to about 3¼ inches in width, the column width of the *Journal*; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHORS' CORRECTIONS

Galley proofs will be sent to the first-named author for corrections after the paper has been scheduled for publication; prompt return (preferably within 48 hours of receipt) is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after he has received the acceptance letter, he should inform the *Journal* office or arrange with a colleague to read the proofs. Authors are urged to keep changes on galleys to a minimum.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be attached to the galley proofs submitted to authors for correction. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

THE AMERICAN PSYCHIATRIC ASSOCIATION

1700 Eighteenth Street, N.W., Washington, D.C. 20009

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication.

TRIAVIL is contraindicated in CNS depression from drugs; in the presence of evidence of bone marrow depression; and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please turn to the following page.

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® **containing perphenazine and amitriptyline HCl**

a tranquilizer-antidepressant

for highly effective relief of depression with moderate anxiety

TRIAVIL®

containing perphenazine and amitriptyline HCl

a tranquilizer-antidepressant

Available:

TRIAVIL® 2-25: Each tablet contains 2 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 2-10: Each tablet contains 2 mg perphenazine and 10 mg amitriptyline HCl

TRIAVIL® 4-25: Each tablet contains 4 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 4-10: Each tablet contains 4 mg perphenazine and 10 mg amitriptyline HCl

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and that the full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude, muscle weakness, mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

For more detailed information, consult your MSD Representative or see full Prescribing Information. Merck Sharp & Dohme, Division of Merck & Co., Inc., West Point, Pa. 19486.

MSD
MERCK SHARP & DOHME

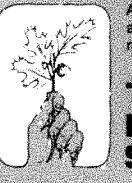
Three Treatment Centers

Three treatment centers provide individually prescribed programs of care, education, treatment and training for children, adolescents and adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.

Advantage: the availability of a **large, trained and experienced staff,** exchanging ideas and insights in a comprehensive program of supportive environment and individualized treatment.

Advantage: **geographically separated** to provide the proper residential milieu . . . yet near enough to benefit from the combined training and experience of a wide range of staff members.

The Oaks — A residential psychiatric treatment center for emotionally disturbed children and adolescents between the ages of six and 18. Coeducational, Austin. In addition, the Center provides a Short Term Adolescent Center and a six bed intensive care unit.



The San Marcos Treatment Center — a facility with three campuses designed for individuals with psychiatric, neurological, and intellectual difficulties who have evidenced a need for a 24-hour therapeutic milieu.

The Center offers a broad spectrum of services to both mentally retarded individuals and those with psychiatric disorders. In addition to a structured therapeutic environment, individual and group psychotherapy services are available to each resident. Clinical supervision and support services are provided by the Center psychiatrists.

The Ranch Treatment Center — located in the suburbs of Austin the Center provides both long-term and intermediate tenure services to multi-handicapped male adolescents and adults whose primary diagnostic classifications are in areas of mental retardation and mental illness. All residents receive program services which may permit their early discharge to the less restrictive settings of community-based programs.

ADAPIN®
(Doxepin HCl)

Capsules, 10 mg., 25 mg., 50 mg.

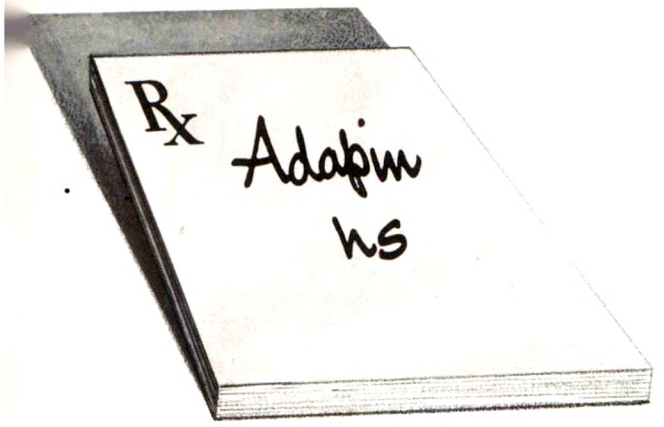
And the Management of Disturbed Sleep Patterns in Anxiety/Depression

Disturbed sleep patterns are a familiar component of the symptom complex seen in patients with anxiety and/or depression.

One study[1] has shown that doxepin [Adapin] is helpful in providing symptomatic relief of sleep disturbances associated with anxiety and depression, "allowing patients to fall asleep more rapidly and feel more rested upon awakening."

Another study[2] points out that doxepin [Adapin] given "at bedtime to outpatients with mixed anxiety and depression will yield as much improvement as can be obtained by giving the drug three times a day."

So, a single dose of Adapin, given at bedtime can often help promote a restful night's sleep for patients with mixed anxiety and depression. Other clinical benefits include:



- rapid antianxiety effect
- distinct clinical brightening of mood—usually within three to four weeks
- low incidence of side effects
- suitability for long-term usage

ADAPIN®

(Doxepin HCl)

Prescribing information:

DESCRIPTION

Adapin (doxepin HCl) is an isomeric mixture of N, N-dimethyl-dibenz(b,e) oxepin- $\Delta^{11(6H)}$, γ propylamine hydrochloride.

ACTIONS

Adapin has a variety of pharmacological actions with its predominant action on the central nervous system. While its mechanism of action is not known, studies have demonstrated that it is neither a monoamine oxidase inhibitor nor a primary stimulant of the central nervous system.

INDICATIONS

In controlled clinical evaluations, **Adapin** has shown marked antianxiety and significant antidepressant effects. **Adapin** has been found to be well tolerated even in elderly patients.

Adapin is indicated for the treatment of patients with:

1. Psychoneurotic anxiety and/or depressive reactions.
2. Mixed symptoms of anxiety and depression.
3. Anxiety and/or depression associated with alcoholism.
4. Anxiety associated with organic disease.
5. Psychotic depressive disorders including involutional depression and manic-depressive reactions.

Target symptoms of psychoneurosis that respond particularly well to **Adapin** include: anxiety, tension, depression, somatic symptoms and concerns, insomnia, guilt, lack of energy, fear, apprehension and worry.

Because **Adapin** provides antidepressant as well as antianxiety effects, it is of particular value in patients in whom anxiety masks depression. Patients who have not responded to other antianxiety or antidepressant drugs may benefit from **Adapin.**

In a large series of patients systematically observed for withdrawal symptoms, none were reported—a finding which is consistent with the virtual absence of euphoria as a side effect and the lack of addictive potential characteristic of this type of chemical compound.

CONTRAINDICATIONS

Because **Adapin** has an anticholinergic effect, it is contraindicated in patients with glaucoma or a tendency toward urinary retention.

Use of **Adapin** is contraindicated in patients who have been found hypersensitive to it.

WARNINGS

Usage in Pregnancy—Adapin has not been evaluated in pregnant patients. Therefore, it should not be used during pregnancy unless, in the judgment of the physician, it is essential to the welfare of the patient.

In animal reproduction studies of **Adapin (doxepin hydrochloride),** gross and microscopic examination of the offspring gave no evidence of drug-related teratogenic effect. Following doses of up to 25 mg./kg./day for 8 to 9 months, no changes were observed in the number of live births, litter size, or lactation. A decreased rate of conception was observed when male rats were given 25 mg./kg./day for prolonged periods—an effect which has occurred with other psychotropic drugs and has been attributed to drug effect on the central and/or autonomic nervous systems.

Usage in Children—The use of **Adapin** in children under 12 years of age is not recommended, because safe conditions for its use have not been established.

MAO Inhibitors—Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with **Adapin.** The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered, and the dosage involved.

PRECAUTIONS

Drowsiness may occur with **Adapin;** therefore, patients should be warned of its possible occurrence and cautioned against driving a motor vehicle or operating hazardous machinery while taking the drug.

Patients should also be cautioned that the effects of alcoholic beverages may be increased.

Since suicide is an inherent risk in depressed patients and remains a risk through the initial phases of improvement, depressed patients should be closely supervised.

Although **Adapin** has shown effective tranquilizing activity, the possibility of activating or unmasking latent psychotic symptoms should be kept in mind.

Compounds structurally related to **Adapin** can block the effects of guanethidine and similarly acting compounds. However, at the usual clinical dosages, 75 mg. to 150 mg. per day, **Adapin** has been given concomitantly with guanethidine without blocking its antihypertensive effect. But at dosages of 300 mg. per day or higher, **Adapin** has exerted a significant blocking effect.

Adapin, like other structurally related psychotropic drugs, potentiates norepinephrine response in animals. But this effect has not been observed with **Adapin** in humans, which is in accord with the low incidence of tachycardia reported clinically.

ADVERSE REACTIONS

Anticholinergic Effects: Dry mouth, blurred vision and constipation have been reported. These are usually mild, and often subside as therapy is continued or dosage reduced.

Central Nervous System Effects: Drowsiness has been observed. It usually occurs early in the course of therapy and tends to subside as therapy continues. (See Dosage and Administration section.)

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported adverse effects include extrapyramidal symptoms, gastrointestinal reactions, secretory effects (such as increased sweating), weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

DOSAGE AND ADMINISTRATION

In most patients with mild to moderate anxiety and/or depression: 10 mg. to 25 mg. t.i.d. to start. A starting dosage of 10 mg. t.i.d. for a period of four days may reduce the initial drowsiness experienced by some patients, and may be tried in cases where drowsiness is clinically undesirable. Decrease or increase the dosage at appropriate intervals according to individual response. Usual optimum dosage is 75 mg. to 150 mg. per day.

In some patients with mild symptomatology or emotional symptoms accompanying organic disease, dosage as low as 25 mg. to 50 mg. per day has provided effective control.

In more severe anxiety and/or depression: 50 mg. t.i.d. may be required to start—if necessary, gradually increase to 300 mg. per day. Additional effectiveness is rarely obtained by exceeding 300 mg. per day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

OVERDOSAGE

Symptoms—An increase of any of the reported adverse reactions, primarily excessive sedation and anticholinergic effects such as blurred vision and dry mouth. Other effects may be: pronounced tachycardia, hypotension and extrapyramidal symptoms.

Treatment—Essentially symptomatic; supportive therapy in the case of hypotension and excessive sedation.

HOW SUPPLIED

Each capsule contains doxepin, as the hydrochloride, 10 mg. (NDC 0018-0356), 25 mg. (NDC 0018-0357), and 50 mg. (NDC 0018-0358) capsules in bottles of 100 and 1000.

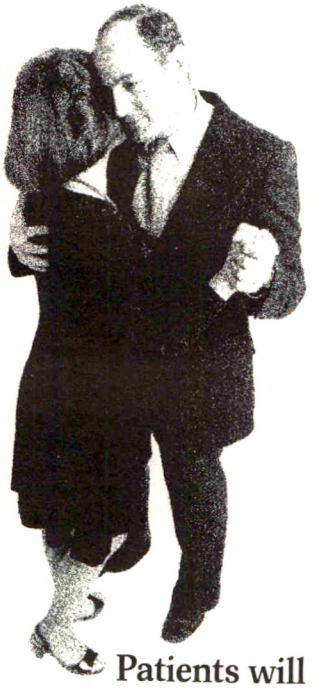
ROCHE

Introducing

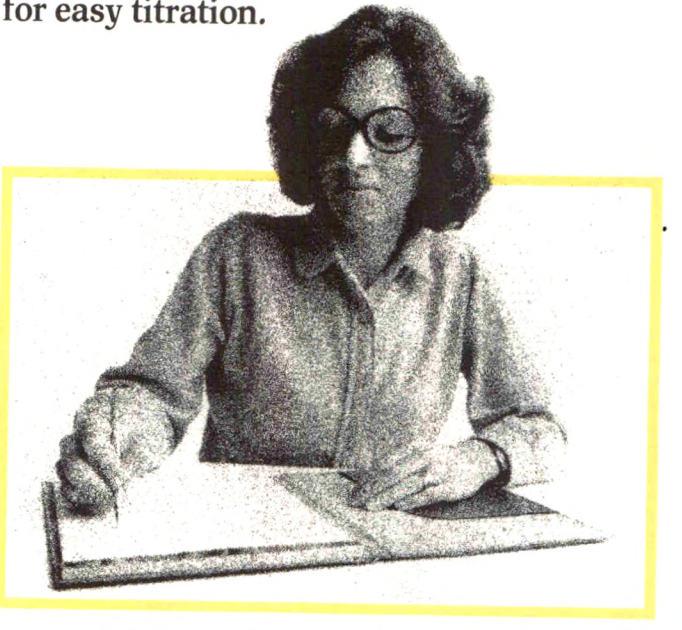
The unforgettable antidepressant

Endep™ 75 mg

amitriptyline HCl/Roche



Here's what makes it unforgettable



Patients are more likely to remember the single bedtime dosage of Endep (amitriptyline HCl).

You'll remember 1 or 2 tablets *h.s.*, because fewer forgotten doses produce a more consistent clinical effect, and because it is the only tricyclic antidepressant scored for easy titration.

Patients will also remember family/interpersonal relationships that they have forgotten or neglected.

In three or four weeks patients will usually remember how well they used to feel.

Endep™ 75 mg

amitriptyline HCl/Roche

The antidepressant you can prescribe at night to work all day

Before prescribing, please consult complete product information, a summary of which appears on the following page.

Introducing Endep™

amitriptyline HCl/Roche

The antidepressant you can prescribe at night to work all day

(orange)	(orange)	(orange)	(yellow)
10-mg scored tablets	**25-mg** scored tablets	**50-mg** scored tablets	**75-mg** scored tablets

■ Endep (amitriptyline HCl), in responsive patients, lifts mood and relieves symptoms such as anorexia, loss of interest, inability to concentrate, decreased libido or GI disturbances, often within three or four weeks after starting therapy.

■ Endep usually relieves accompanying sleep disturbances, particularly early in the treatment regimen.

■ All four dosage strengths are scored for greater flexibility and convenience in titration.

■ The 75-mg *h.s.* dose minimizes skipped doses, maximizes patient acceptance and compliance.

■ Specifying Endep/Roche assures quality plus potential economy.

Important Considerations

Should not be given concomitantly with an MAO inhibitor.

Not recommended for use during the acute recovery phase following myocardial infarction.

Contraindicated in patients with hypersensitivity to amitriptyline.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: To relieve symptoms of depression (notably endogenous depression) and depression accompanied by anxiety.

Contraindications: Known hypersensitivity. Do not use with monoamine oxidase (MAO) inhibitors or within at least 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Use not recommended during acute recovery phase after myocardial infarction.

Warnings: May block action of guanethidine or similar antihypertensives. Use with caution in patients with history of seizures, urinary retention, angle closure glaucoma, increased intraocular pressure. Closely supervise cardiovascular patients, hyperthyroid patients and those receiving thyroid medications. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, including amitriptyline HCl, especially in high doses. Myocardial infarction and stroke reported with use of this class of drugs.) May impair alertness; warn against hazardous occupations or driving a motor vehicle during therapy. Weigh potential benefits against hazards during pregnancy, the nursing period and in women of childbearing potential. Not recommended in children under 12.

Precautions: May exaggerate symptoms in schizophrenic and paranoid patients, or shift manic-depressives to manic stage; reduce dose or administer major tranquilizer concomitantly. Close supervision and careful dose adjustments required when given with anticholinergic or sympathomimetic agents. Exercise care in patients receiving large doses of ethchlorvynol; transient delirium reported with concomitant administration. May enhance effects of alcohol, barbiturates and other CNS depressants. Because of the possibility of suicide in depressed patients, do not permit easy access to large drug quantities in these patients. Because it may increase hazards of electroshock therapy, limit concomitant use to essential treatment. If possible, discontinue drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: Note: This list includes a few adverse reactions not reported with this specific drug but requiring consideration because of similarities of tricyclic antidepressants. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, eosinophilia. purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue. *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, jaundice, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache and malaise. These are not indicative of addiction.

Dosage: Initiate at low levels; increase gradually, watching for signs of intolerance. As long as 30 days may elapse before adequate antidepressant effect develops; sedative effect may be noted earlier. *Initial Adult Dosage:* Outpatients – 25 mg t.i.d.; may be increased to 150 mg/day. Add increased drug to afternoon and/or bedtime doses. Alternate – 50 to 100 mg h.s., gradually increasing h.s. dose up to 150 mg/day. Hospitalized Patients – Up to 100 mg/day; increase gradually to 200 mg if necessary. A few patients may require 300 mg/day. *Adolescent and Elderly Patients:* In general, 10 mg t.i.d. with 20 mg h.s. may be satisfactory for those who do not tolerate higher doses. *Maintenance Dosage:* With symptomatic improvement, reduce dosage to lowest amount that gives relief, usually 25 mg b.i.d. to q.i.d., or 10 mg q.i.d. Continue maintenance therapy 3 months or longer to avoid relapse.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. IV administration of 1 to 3 mg physostigmine salicylate reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestations and treatment.

Supplied: 10-mg, 25-mg, 50-mg and 75-mg scored tablets – bottles of 100 and 500; Prescription Paks of 60 (10 mg, 25 mg and 50 mg) or 30 (75 mg), available singly and in trays of 10.

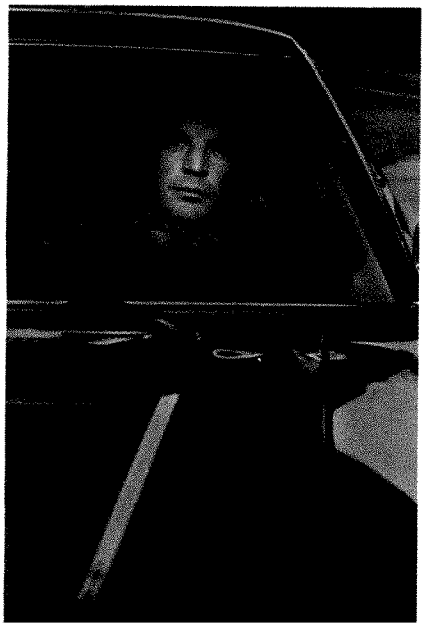
Drunken driving is the cause of an estimated 28,000 auto accident deaths each year—approximately half of these fatal accidents involve an alcoholic. This is only one aspect of the staggering problem represented by alcoholism—perhaps this country's most neglected disease.

Yet, it needn't be, for alcoholism is treatable. Through early detection and treatment of the alcoholic, as well as the use of community resources, physicians can exert a major force in the control and reduction of alcoholism.

ANTABUSE (disulfiram) can help. It offers strong deterrent action...helping alcoholic patients maintain a state of sobriety, while they participate in a total treatment program. Your patient should know the consequences of even a single drink while taking this medication. ANTABUSE works by blocking the normal degradation of alcohol, sharply increasing the concentration of acetaldehyde in the blood by 5 to 10 times, and setting off a most unpleasant, though temporary reaction.

ANTABUSE helps strengthen your patient's resolve...while you help with his underlying problem. On ANTABUSE therapy, the alcoholic patient functions more effectively—not only behind the wheel, but also at work and at home.

BRIEF SUMMARY
(For full prescribing information, see package circular.)
ANTABUSE® (disulfiram) In Alcoholism
INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)
CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, *e.g.* cough syrups, tonics, and the like, should not be given ANTABUSE.
ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity.



WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.
The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.
THE ANTABUSE-ALCOHOL REACTION:
ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.
The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.
The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.
DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.
Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.
It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.
Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.
CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.
USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.
PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)
Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.
Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.
ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)
Optic neuritis, peripheral neuritis, and polyneuritis may occur following administration of ANTABUSE.
Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.
In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.
Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.
One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.
DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.
INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.
MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.
NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.
DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.
TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.
However, where a test reaction is deemed necessary, the suggested procedure is as follows:
After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (1/2 oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.
MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.
HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100.
No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000. **7626**

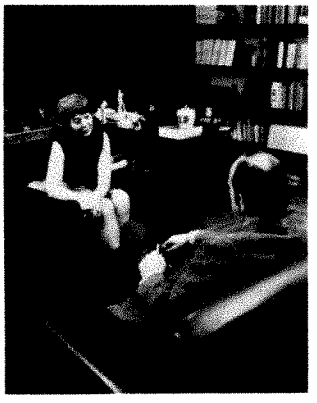
Haldol®
(haloperidol)
tablets/concentrate/injection

For prompt control with minimal risk of hypotension or oversedation

Highly effective in a wide range of psychotic symptoms[1-7]
such as hallucinations, delusions, suspiciousness, hostility, mania, psychomotor agitation, etc., in both acute and chronic disorders.

Helps keep patients functioning and avoid hospitalization.[1-3]
HALDOL haloperidol usually leaves most patients alert and responsive, able to function at work and at home without impairment, and more amenable to other therapeutic measures.

Permits aggressive titration to effective dosage levels[1,4]
up to 100 mg/day orally (with minimal risk of usual troublesome reactions) to achieve optimal response when patient is inadequately controlled at lower dosage...to help you rapidly control and stabilize new patients, promptly regain control during periods of exacerbation.



Common side effects easily controlled.[1,2,4]
Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Reduces risk of certain troublesome reactions.[1,2,4-6]
Transient hypotension occurs rarely and severe orthostatic hypotension has not been reported. Marked sedation is rare, although some instances of drowsiness have been reported. In addition, with chronic use, it is unlikely to cause hepatic damage, serious hematologic reactions, photosensitivity reactions and skin rashes...and has minimal effect on renal function.

Please turn page for information relating to Indications, Contraindications, Warnings, Precautions and Adverse Reactions.

Important: Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

Haldol® (haloperidol)

tablets/concentrate/injection

For prompt control of psychotic symptoms with minimal risk of hypotension or oversedation

A Dosage Form for Every Need:

5 tablet strengths for convenience in individualizing dosage: ½ mg., 1 mg., 2 mg., 5 mg. and 10 mg.

A tasteless, odorless, colorless liquid concentrate for better patient acceptability: 2 mg. per ml.

A rapid-acting injection for psychiatric emergencies: 5 mg. per ml., with 1.8 mg. methylparaben and 0.2 mg. propylparaben per ml., and lactic acid for pH adjustment to 3.4±0.2.

Indications: HALDOL haloperidol is indicated for use in the management of manifestations of psychotic disorders.

It is also indicated for the control of tics and vocal utterances of Gilles de la Tourette's syndrome.

Contraindications: HALDOL haloperidol is contraindicated in patients who are severely depressed, comatose, have CNS depression due to alcohol or other centrally-acting depressants, have Parkinson's disease or are hypersensitive to this drug.

Warnings: ***Usage in Pregnancy:*** Safe use of HALDOL haloperidol in pregnancy and lactation has not been established; therefore, its use in pregnancy, in nursing mothers, or in women of childbearing potential requires that the possible benefits of the drug be weighed against the potential hazards. A case of phocomelia in an infant whose mother received haloperidol along with a number of other medications during the first trimester of pregnancy has been reported (a causal relationship was not established in this case). Animals receiving 2 to 20 times the maximum human dose of haloperidol orally and/or parenterally showed increased incidence of resorption, reduced fertility, delayed delivery, dose-related pup mortality (presumably due to lack of maternal care reflecting CNS depression).

Usage in Children: Safety and effectiveness in children have not been established; therefore, this drug is not recommended for use in the pediatric age group.

General: Cases of bronchopneumonia, some fatal, have followed the use of major tranquilizers, including haloperidol. It has been postulated that lethargy and decreased sensation of thirst may lead to dehydration, hemoconcentration and reduced pulmonary ventilation. If these signs and symptoms appear, especially in the elderly, the physician should institute remedial therapy promptly. Although not reported with HALDOL haloperidol, decreased serum cholesterol and/or cutaneous and ocular changes have been reported in patients receiving chemically-related drugs. HALDOL haloperidol may impair the mental and/or physical abilities required for the performance of hazardous tasks such as operating machinery or driving a motor vehicle. The ambulatory patient should be warned accordingly. The use of alcohol should be avoided due to possible additive effects and hypotension.

Precautions: HALDOL haloperidol should be administered cautiously to patients: (1)—with severe cardiovascular disorders, because of the possibility of transient hypotension and/or precipitation of anginal pain. Should hypotension occur and a vasopressor be required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxically further lowering of blood pressure may occur. (2)—receiving anticonvulsant medication, because HALDOL haloperidol may lower the convulsive threshold. Adequate anticonvulsant therapy should be maintained concomitantly. (3)—with known allergies, or with a history of allergic reactions to drugs. (4)—receiving anticoagulants, since an isolated instance of interference occurred with the effects of one anticoagulant (phenindione).

If concomitant antiparkinson medication is required, it may have to be continued after HALDOL haloperidol is discontinued because of the difference in excretion rates. If both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson agents, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used to control mania in cyclic disorders there may be a rapid mood swing to depression.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions*—Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which usually were mild to moderately severe and reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Administration of antiparkinson drugs may be required for control of such reactions. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases. *Persistent Tardive Dyskinesia*—Tardive dyskinesia may appear during long-term therapy or after therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. There is no known effective treatment. All antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent. *Other CNS Effects*—Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms including hallucinations. ***Cardiovascular Effects:*** Tachycardia and hypotension. ***Hematologic Effects:*** Reports have appeared of mild and usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis. Agranulocytosis has rarely been reported and then only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice have been reported, although a causal relationship has not been established. ***Dermatologic Reactions:*** Maculopapular and acneiform skin reactions and isolated cases of photosensitivity and loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

Complete dosage information available in insert which accompanies each package (or on request).

The use of the injectable form is intended for the acutely agitated psychotic patient with moderately severe to very severe symptoms.

IMPORTANT: Full directions for use should be read before HALDOL haloperidol is administered or prescribed. 9/74

CHARLES C THOMAS • PUBLISHER

OBESITY: Etiology, Treatment and Management *edited by* **Milton V. Kline,** *The Institute for Research in Hypnosis, New York;* **Lester L. Coleman,** *Albert Einstein College of Medicine, New York; and* **Erika E. Wick,** *St. John's Univ., Jamaica, New York. (39 Contributors)* In addition to full clinical coverage, material is presented on classification of obesity within a psychodynamic and clinical orientation, and types of obesity which are encountered in the daily practice of psychotherapy and medicine. *'76, 480 pp., 14 il., 34 tables, $21.75*

IDENTITY GROUP PSYCHOTHERAPY WITH ADOLESCENTS *by* **Arnold W. Rachman,** *New York, New York.* The main objective of this book is to present a unique, relevant, contemporary theory of group psychotherapy with adolescents. The author presents an enthusiastic, positive feeling while at the same time he is aware of the realistic difficulties and concerns about working with adolescents in groups. *'75, 336 pp., $16.75*

FORENSIC PSYCHIATRY: A Practical Guide for Lawyers and Psychiatrists *by* **Robert L. Sadoff,** *Univ. of Pennsylvania, Philadelphia.* This book is designed as a practical guide for lawyers and psychiatrists working together in areas of mental competency, criminal responsibility, domestic relations, commitment procedures, traumatic illnesses, drug and alcohol problems, sexual matters and juvenile crimes. Case citations and a psychiatric glossary are provided for the lawyer; outlines of interviews and forensic psychiatric reports are included for the psychiatrist. *'75, 272 pp., $14.50*

GESTALT THERAPY PRIMER: Introductory Readings in Gestalt Therapy *edited by* **F. Douglas Stephenson,** *Consultation and Guidance Services and Gestalt Institute of North Florida, Gainesville. Foreword by* **Vincent O'Connell.** *(11 Contributors)* A basic introduction is provided in this book to the philosophy, methods and practice of Gestalt psychotherapy. Key theoretical principles discussed include awareness, contact, figure/ground formation and polarities, and the therapeutic use of fantasy and dream. *'75, 232 pp., 2 il., $16.50, paper*

TOWARD SELF-UNDERSTANDING: Group Techniques in Self-Confrontation (4th Ptg.) *by* **Daniel I. Malamud,** *New York Univ., New York, and* **Solomon Machover,** *State Univ. of New York, Brooklyn.* Planned, open-ended procedures designed to excite the participants' curiosity about significant aspects of themselves are presented in three areas: formative influences in childhood, personal characteristics and processes, and interpersonal relations. *'75, 288 pp., $10.95*

A PRIMER ON SCHOOL MENTAL HEALTH CONSULTATION *by* **Morton I. Berkowitz,** *Univ. of Pittsburgh, Pittsburgh, Pennsylvania.* The author describes the consultation process from its beginning to its completion. Emphasis is placed on special aspects of consultation within the school system, consultant-consultee interaction and levels of prevention. *'75, 132 pp., $10.00*

REHABILITATION MEDICINE AND PSYCHIATRY *edited by* **Jack Meislin,** *Albert Einstein College of Medicine, Bronx, New York. Foreword by* **Walter E. Barton.** *(29 Contributors)* In this book, emphasis is placed on the application of a holistic approach to the rehabilitation of the mentally ill. After defining terms and identifying goals, the authors describe process and methodology. Behavior modification, reality orientation and numerous other techniques are described as well as nonverbal communication. *'76, 564 pp. 1 il., 12 tables, $24.75*

PSYCHIATRY AND THE CRIMINAL: A Guide to Psychiatric Examinations for the Criminal Courts (3rd Ed.) *by* **John M. Macdonald,** *Univ. of Colorado, Denver. Chapter by* **Leighton C. Whitaker.** This book reviews the origins of crime, tests of criminal responsibility and competency to stand trial, evaluation of dangerousness, simulation of mental disorder, and other special problems presented by those who break the law. *'76, 524 pp., 2 tables, $28.50*

RAPE IN PRISON *by* **Anthony M. Scacco, Jr.,** *Educational Criminologist, Waterbury, Connecticut.* Emphasis is placed in this book on juvenile and young adult institutions. Covered are such topics as the institutional setting and how this contributes to sexual aggression, the sexual acts themselves within the institutions, the victims and who they are, inside violence discussed as a possible microcosm of outside society, and alternatives for change. *'75, 144 pp. (5 3/8 x 8 1/2), $10.50*

THE VARIETIES OF ABNORMALITY: A Phenomenological Analysis *by* **Raymond J. McCall,** *Marquette Univ., Milwaukee, Wisconsin.* The philosophical conception of the nature of human abnormality is discussed in this volume along with the concepts of psychological defense, neurotic symptoms and neurosis, personality pattern disturbances and functional psychoses. Character disorders are examined in detail. *'75, 592 pp., 4 il., cloth-$22.50, paper-$16.95*

CHILDREN'S SPATIAL DEVELOPMENT *compiled and edited by* **John Eliot,** *Univ. of Maryland, College Park, and* **Neil J. Salkind,** *Univ. of Kansas, Lawrence. (4 Contributors)* Comprised of four essays, this book discusses a status description of genetic studies of spatial behavior, a review of studies of neurological influences, a statement describing research on the language of space, and the relation of spatial development to the study of child development. *'75, 312 pp., 24 il., 3 tables, $23.50*

ART AND HUMAN EMOTIONS *by* **Egon Weiner,** *Chicago Art Institute, Chicago, Illinois. Foreword by* **Jules H. Masserman.** The author of this book opens doors to the knowledge of art and its meaning and communicates his ideas which encompass a wide range of experience, based on many years of traveling and working as an artist, teacher and lecturer. Emotional perception of subjective meanings and poetic interrelationships are discussed along with such topics as modern sculpture, creative abilities of the artist, and symbolism in art. *'75, 104 pp., 6 il., $6.75*

Valium® (diazepam) is a benzodiazepine with a character all its own. Pharmacologically, it has been described as more potent mg-per-mg than other available anxiolytic benzodiazepines. Pharmacokinetically, only Valium provides active *diazepam* as well as the active metabolites 3-hydroxydiazepam, desmethyldiazepam and oxazepam.

But the individual character of Valium is even more apparent clinically. And far more significant. That's because of the patient response obtained with Valium. A response which brings a calmer frame of mind. A response which has a pronounced effect on the somatic symptoms of anxiety, particularly muscular tension. A response which helps the patient feel more like himself again because of the way Valium reduces the overwhelming symptoms of anxiety and psychic tension.

Another important aspect of the clinical character of Valium (diazepam) is safety. Though drowsiness, ataxia and fatigue are possible, these and more serious side effects are rarely a problem. Of course, as with all CNS-acting drugs, patients taking Valium should be cautioned against driving, operating dangerous machinery or consuming alcoholic beverages.

Unquestionably, many psychotherapeutic agents, including other benzodiazepines, have antianxiety effects. But one fact remains: you get a certain kind of patient response with Valium. It's a response you want. A response you know. A response you trust as part of your overall management of anxiety and psychic tension.

A prudent choice in psychic tension and anxiety.

Please turn page for a summary of product information.

ROCHE

Valium® (diazepam) Ⓥ
has a character all its own.

2-mg, 5-mg, 10-mg scored tablets

Initial calming in hours. Your anxious patient will be reassured by the prompt action of Valium. It's immediate, tangible proof that the medication is working.

Significant improvement in days. Because of the way Valium reduces the overwhelming symptoms of anxiety and psychic tension, your patient begins to feel more like himself again often within a few days.

Patient response you know, want and trust. You get a certain kind of response with Valium. It's a pronounced response. A response which, by its very nature, quickly begins to restore the patient's lost sense of well-being. And, of course, at recommended dosages, Valium offers a wide margin of safety.

Pharmacokinetic predictability. Valium has demonstrated a highly reliable and consistent pattern of absorption, distribution, metabolism and excretion—one more indication of its overall reliability of performance.

Before prescribing, please consult complete product information, a summary of which follows:

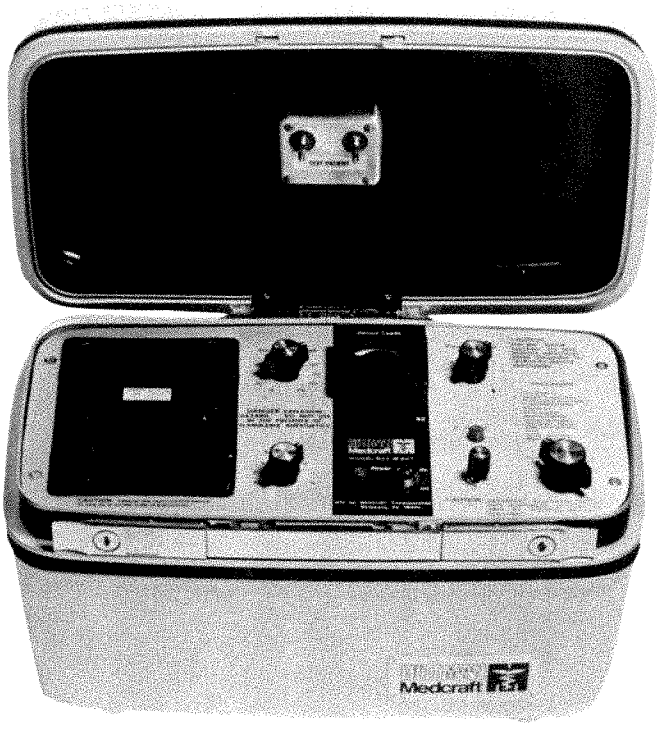
Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.



Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10.

The B24 III

UL LISTED

...a new generation of electroconvulsive therapy instrumentation from Medcraft.

Designed with patient and operator safety in mind, this new series of instrumentation meets the rigorous requirements for listing by Underwriters Laboratories — UL 544, Standards for Medical and Dental Equipment. The B24 III provides the physician with the ultimate in precision dosage levels. Consistancy of desired output level is assured with the following features:

- Line Voltage Compensation — allows compensation for fluctuations in incoming line voltages.
- Pre-programmed Voltage Selection — choice of eleven voltage levels from 70 volts to 170 volts.
- Automatic Treatment Timing — adjustable from 0.1 second to 1.0 second with or without Glissando.
- Current Output Indicators — visual assurance of current flow during treatment.

Exclusive Patient Test Module allows a complete systems integrity check of instrumentation prior to treatment. Clinical accuracy and dependability are assured by the use of 100% solid state circuitry. Double shielded transformer provides an additional margin of treatment safety. The vulnerable ages

The first epileptic seizure is most likely to occur during early childhood and at the onset of puberty

About 9 out of 10 epileptics experience their first seizure before the age of 20—with the highest incidence between 5 and 7, when children start school, and at the onset of puberty, a time of physiological and psychic turmoil.[1] The most common type, grand mal, occurs in approximately 75% of epileptic children,[1] and more than 50% of patients who suffer initially from petit mal develop grand mal seizures before they reach the age of 16.[2]

Mysoline (primidone) for control of grand mal, psychomotor and focal epilepsy

At the onset and afterwards—used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. *Excellent* for control of grand mal. Valuable for control of psychomotor[1,3,4] and focal epilepsy as well.[5]

Add Mysoline when control with other anticonvulsants is inadequate—As concomitant therapy, MYSOLINE can improve seizure control in grand mal and psychomotor epilepsy. The combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.[6]

Change to Mysoline when other anticonvulsants fail—A changeover to MYSOLINE is frequently warranted when other anticonvulsants must be discontinued because of important side effects, or when grand mal seizures are refractory to phenobarbital, with or without diphenylhydantoin.[7]

Mysoline® (primidone)

may be the start of a better life for the epileptic

initial and maintenance therapy for
grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY
(For full prescribing information, see package circular.)

MYSOLINE® Brand of PRIMIDONE
Anticonvulsant

ACTIONS: MYSOLINE acts on the central nervous system to raise seizure threshold or alter seizure pattern. The mechanism(s) of action of anticonvulsant drugs is not known.

Primidone has anticonvulsant activity *per se*. In addition, its two metabolites possess anticonvulsant qualities. The major metabolite is phenylethylmalonamide (PEMA); the other is phenobarbital. In addition to its own anticonvulsant potential, PEMA potentiates phenobarbital.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several days before it can be assessed.

Use in pregnancy: Recent reports strongly suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Reference has been made to primidone in several cases in which it was used *in combination* with other anticonvulsants; but its teratogenicity has not been conclusively demonstrated. The possibility exists that other factors, *e.g.*, genetic factors or the epileptic condition, may contribute to the higher incidence of birth defects. The data also indicate that the great majority of mothers receiving anticonvulsant medication deliver normal infants.

Anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and risk to both mother and the unborn child.

When the nature, frequency, and severity of the seizures do not pose a clear threat to the patient, good medical practice requires that the physician weigh the expected therapeutic benefit of anticonvulsant therapy against possible risk on an individual basis.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K therapy for one month prior to, and during, delivery.

The physician should weigh all of the foregoing considerations when treating and counseling epileptic women of childbearing potential.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

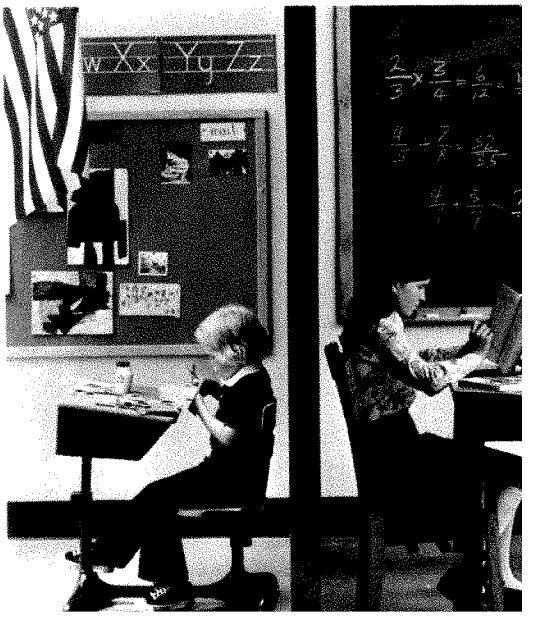
ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 mg. Increments of 250 mg. are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 Gm. A typical dosage schedule for the introduction of MYSOLINE (primidone) is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg., with gradual weekly increases of 125 mg. a day, to a daily total usually between 500 mg. and 750 mg.



In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances:

- for initiation of combination therapy
- during "transfer" therapy
- for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.)

HOW SUPPLIED: MYSOLINE *Tablets*—No. 430—Each tablet contains 250 mg. of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg. of primidone (scored), in bottles of 100 and 500. MYSOLINE *Suspension*—No. 3850—Each 5 cc. (teaspoonful) contains 250 mg. of primidone, in bottles of 8 fluid-ounces.

I CLI ICALLY SIG IFICA T DEPRESSIVE NEUROSIS...

For Brief Summary, please see following page.

SANDOZ

75-379

RESULTS OFTEN SEEN IN A WEEK

Because the somatic and psychic complaints that accompany depressive neurosis can interfere with the treatment of the underlying psychopathology—rapid relief of these symptoms is often crucial to therapy.

In 14 double-blind studies of four weeks duration, 339 patients with depressive neurosis received Mellaril. In these studies, 55% of the overall improvement was observed by the end of the first week, and a total of 293 patients (86%) improved during the four weeks.*

Mellaril usually does not cause euphoria or undue sedation and is nonaddicting. Patients, therefore, generally remain alert and better able to respond to therapy. (The physician should, however, caution patients against participating in activities which require complete mental alertness, e.g., driving.)

*Data on file at Sandoz Pharmaceuticals.

MELLARIL® (THIORIDAZINE)

TABLETS: 25 mg and 50 mg thioridazine HCl, U.S.P.

for the short-term treatment of moderate to marked depression with variable degrees of anxiety in patients with depressive neurosis

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling. The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Dosage: Dosage must be individualized according to the degree of mental and emotional disturbance, and the smallest effective dosage should be determined for each patient. In adults with depressive neurosis the usual starting dosage is 25 mg t.i.d. and the dosage ranges from 10 mg b.i.d. to q.i.d. in milder cases to 50 mg t.i.d. or q.i.d. for more severely disturbed patients; the total daily dose ranges from 20 mg to a maximum of 200 mg.

THE AMERICAN JOURNAL OF PSYCHIATRY

The Syndrome of Autism: A Critical Review

BY EDWARD M. ORNITZ, M.D., AND EDWARD R. RITVO, M.D.

The authors review the clinical features and behavioral characteristics of autism; differential diagnosis of the syndrome; clinical, neurophysiological, and biochemical research; and its medical management and treatment. They conclude that autism is a behaviorally defined, specific syndrome that is manifested at birth or shortly thereafter. Its symptoms are expressive of an underlying neuropathophysiological process that affects developmental rate; modulation of perception; language, cognitive, and intellectual development; and the ability to relate. The long-term prognosis is guarded; almost all patients manifest severe symptomatology throughout their lives. Further basic research into the neuropathophysiological process underlying the syndrome is necessary in order to reach the ultimate goal of developing etiologically specific treatment programs.

OF ALL THE SYNDROMES now classified as developmental disabilities, autism is one of the most difficult to understand. Wide differences in severity, periodic changes of the symptoms (1, 2), confusing and inconsistent nosology, and the lack of specific physical signs make diagnosis a difficult procedure. The behavior of autistic children is bewildering to parents, and thus it is often difficult to obtain an adequate developmental history. Unless the physician suspects autism and knows which symptoms and signs to elicit, the diagnostic process may be thwarted from the outset. Too often parents are told, "Let's wait, he is just slow in developing and will probably catch up soon."

Initial parental concern arises at different ages. A particularly observant mother may comment to her pediatrician that her 2-month-old reacts very differently than her other children did. At the other extreme are parents who do not seek medical attention until their child is 6 or 7. Most patients are usually first evaluated when 2 to 3 years old. The most frequent initial complaint is that of a delay in speech development, earlier and more subtle symptoms having been overlooked or denied. Thus autism must always be included in the differential diagnosis when one is evaluating any child with a developmental disability.

DIAGNOSTIC TERMINOLOGY

The syndrome of autism was first identified by Kanner in 1943 when he described a group of children as having "autistic disturbances of affective contact" (3). In 1944 he adopted the term "early infantile autism" and drew attention to the fact that its symptoms occurred in early infancy (4). The term "autism" and its synonyms—"childhood autism," "primary autism," "infantile autism," and "autistic child"—have become the most commonly accepted ways of referring to this condition.

"Atypical development" and "atypical ego development" have been used by psychoanalytically oriented investigators to describe similar patients (5–7). The term "symbiotic psychosis" has also been used to de-

This paper was written at the invitation of the Editor.

scribe children who are similar in many ways but who may relate differently (8). These patients at times cling tenaciously to their parents. Since this clinging behavior can alternate with emotional unresponsiveness, this term does not necessarily describe an independent disorder (2).

The labels "pseudo-retarded" and "pseudo-defective" have been used to emphasize the differences between "typical" or "simple" mental retardation and autism (9, 10). Since studies (11, 12) have demonstrated that most autistic children have intellectual and cognitive delays, these terms are not sufficiently specific to be clinically useful. The more general and less well-defined terms "infantile psychosis," "childhood psychosis," and "early onset psychosis" are also used extensively (6, 7, 11–20). They emphasize psychological damage to the developing personality of the child and, depending on the investigator, may or may not overlap with "autism."

Finally, a term that is also widely used for similar patients is "childhood schizophrenia" (1, 9, 10, 21–26). Semantic confusion and controversy exist with regard to the use of this label. Certain investigators view autism as phenomenologically distinct from adult forms of schizophrenia (16–19, 27). Others postulate a continuum of disease process from childhood to adulthood (9, 15, 28–30). The distinctions and similarities between patients labeled autistic and schizophrenic will be discussed later. Articles referring to childhood schizophrenia and schizophrenic children will be cited in this review when the clinical features of the patients conform to those described in the following section.

CLINICAL FEATURES OF THE AUTISTIC SYNDROME

Age of Onset

Autism is probably present at birth. Since the first symptoms may not be recognized or recalled by parents, two courses of the illness have been reported. In the first, deviant behavior is noted shortly after birth even though mothers are not always able to specify the subtle nature of their infants' "strange behavior." The infants may cry infrequently, not respond to companionship, and apparently not need stimulation. They become limp or rigid when held and are often described as "very good babies" who never fuss. On the other hand, they may be intensely irritable and overreact to any form of stimulation and may have flaccid muscle tone. In the second course of development, the parents report relatively normal development up to 18 to 24 months, at which time they first note symptoms. The obvious appearance of symptoms invariably occurs before 30 months of age (2, 16, 18). In our experience, the subsequent clinical course is the same regardless of the age at which symptoms are first reported. A recent report (31) of better prognosis when the apparent onset of symptoms is delayed suggests that symptoms are not recognized at birth in milder forms of the illness.

Very careful history-taking usually elicits the fact that subtle signs did indeed occur during the first year of life. These may be forgotten, overlooked, or denied due to parental anxiety or unfamiliarity with normal development.

Behavioral Characteristics

The behavioral symptoms of autism can be separated into the following five subclusters. These include disturbances of perception, developmental rate, relating, speech and language, and motility.

1. *Disturbances of perception.* Disturbances of perception are most likely due to an underlying neuropathophysiological process that is common to all autistic patients (32). It results in faulty modulation of external sensory input (2, 29, 33), distortion of the normal hierarchy of receptor preferences (34), and an impaired ability to use internal sensory input to make discriminations in the absence of feedback from motor responses (35).

The failure of adequate modulation of sensory input constitutes a striking and unique aspect of autism (2, 25, 33, 34, 36). Behaviorally, it appears as hyporesponsive or hyperresponsive states that alternate in the same child (25, 26). When hyporeactivity to auditory stimuli occurs, the patient does not react to either verbal commands or sounds. There may be no startle response to very loud sudden noises (37) and delayed attention to those (personal observation) and other sounds (38). The patient may have no visual reaction to new persons or objects in the environment, and he may walk into objects as if he did not see them. A similar lack of response to tactile and painful stimuli frequently occurs during the first two years of life: objects placed in the hand fall away, and painful stimuli such as bruises, cuts, and injections may evoke no reaction.

Contrasting starkly to such hyporeactivity are decidedly exaggerated reactions to the same stimuli. In this state, patients show heightened *awareness* and heightened *sensitivity* to stimuli (25). They may also seek out stimulation. Behaviors such as making sounds by scratching surfaces while putting the ears close to listen, being distracted by background stimuli of marginal intensity, rubbing, banging, or flicking at the ears, and teeth-grinding are all activities that induce auditory input. Visually, autistic patients may regard their hand and finger movements and scrutinize fine details of surfaces and have brief episodes of intense staring. They may induce tactile input by rubbing the surfaces of furniture or fabrics. Many behaviors suggest that they are actively inducing vestibular and proprioceptive stimulation (9, 10). For example, whirling, rocking, and head-rolling are common. Repetitive handflapping also may provide proprioceptive input.

One can often observe distress induced by routine stimuli in all sensory modalities. When in such a state, a child may become severely agitated by a siren, a vacuum cleaner, or a barking dog. He may cup his hands

over his ears in an attempt to shut out such intense sounds (25, 33). Sudden changes in illumination or confrontation with an unexpected object may elicit similar fearful reactions. In the tactile mode, the autistic patient may suddenly develop a severe intolerance for certain fabrics, and the introduction of rough-textured foods may evoke distress. The child who whirls himself may at other times show a pronounced aversion to vestibular stimulation induced by roughhouse play or riding in a car or elevator.

Autistic patients have been described as showing a preference for proximal receptors (touch, smell, and taste) rather than distal receptors (hearing and seeing) (34, 39). They also have been shown to have fewer eye movements and to spend less time regarding visual displays than do nonautistic individuals (35). Many autistic patients who have normal or even advanced form perception (40) make poor use of visual discrimination when learning. It has been observed that they are more dependent than normal individuals on feedback from their motor responses to make sense out of their perceptions (35).

2. *Disturbances of developmental rate.* Autistic children show deviations from the normal sequential motor, language, and social milestones (1). In particular, the even course of normal development is disrupted (41). For example, an autistic child may precociously sit without support but be delayed in pulling himself up to a standing position. Sequences of spurts and plateaus are characteristic (1), as are the "special abilities" of some otherwise very retarded autistic children (42). These observations can be used to distinguish them from other types of severe retardation (43).

3. *Disturbances of relating.* Behaviors that indicate disturbances of relating are due to arrests or developmental delays in personality formation. Behaviors indicative of such ego pathology include poor or deviant eye contact (44); delayed or absent social smile; delayed or absent anticipatory response to being picked up (3); apparent aversion to physical contact; a tendency to react to only a part of another person; disinterest in playing games with others; and delayed, absent, or overreactive anxiety to strangers (27). Disturbances in relating may be subtle and intermittent.

Experiments conducted under well-controlled laboratory conditions suggest that disturbed relatedness in autism may be secondary to disturbances of perception (35). Disturbed relatedness to objects is expressed by flicking, twirling, and spinning toys rather than using them in an apperceptive manner. This observation led Kanner and Eisenberg (3, 45) to conclude that these children wanted "to maintain sameness in their environment." We believe that they are upset by observing different perceptual sets and hence try to maintain "sameness." With increasing age, the autistic child's disturbances in relatedness lead to rigidity and inflexibility in the use of play material (46), inability to form peer relationships, and intermittent responsiveness to parents.

4. *Disturbances of speech and language.* Speech and language development may be totally delayed (muteness), or fixations may occur along the normal course of development (3, 10, 47). Echolalia is a common feature and is usually accompanied by the misuse or reversal of pronouns (3, 27). Echoing of feelings as well as words occurs. When functional speech develops, it is usually atonal and arrhythmic, lacking inflection and failing to convey subtle emotion (26). The atonal and poor affective qualities of speech in young autistic children usually persist into adulthood even in those few children who develop communicative language.

5. *Disturbances of motility.* The strange and bizarre appearance of many autistic children is due to their peculiar mannerisms and patterns of motility. These may be complex and repeated serially (stereotypies), and they do not appear to be involuntary movements typical of seizure patterns. Disturbances of motility may appear intermittently in some autistic children; these disturbances may be continuously present in others (48, 49).

The most typical motility disturbance involves the hands and arms (2, 48). The hands usually are moved within the visual field. Laboratory studies have demonstrated that the motility disturbance of the hands (hand-flapping and oscillating) occurs at the same frequency over time and that groups of patients flap at the same rate (50). Furthermore, these behaviors are relatively unaffected by environmental factors such as the presence of other persons or toys (51). These studies have led us to conclude that disturbances in motility can best be understood as an expression of a central nervous system (CNS) dysfunction. Some researchers have explored the possible significance of the relationship between motility and perceptual disturbances for a neuropathophysiological explanation of autism (36, 52, 53). Motility disturbances may also involve the feet, as in the case of toe-walking. Toe-walking is frequently intermittent while the autistic child is running, but it may also be continuous (54).

Motility disturbances of the trunk and the body include staccato lunging and darting movements, body-rocking and swaying, and head-rolling or head-banging. These disturbances are not constant and do not have the persistent, irritable quality typical of children labeled "hyperactive." In fact, the motility patterns of autistics are usually interrupted by episodes of immobility and posturing. For example, patients less than 3 years of age may be observed to arch the back and hyperextend the neck for several minutes at a time.

When examining a patient, we have him look at a spinning top. This frequently elicits motility disturbances such as hand-flapping, posturing, and twirling.

A detailed behavioral description of symptoms is important in order to avoid misdiagnosis. Nonspecific descriptions such as "the child shows bizarre behaviors" are insufficient. We have found that the accuracy of diagnosis is enhanced by our conducting at least three separate diagnostic examinations at weekly inter-

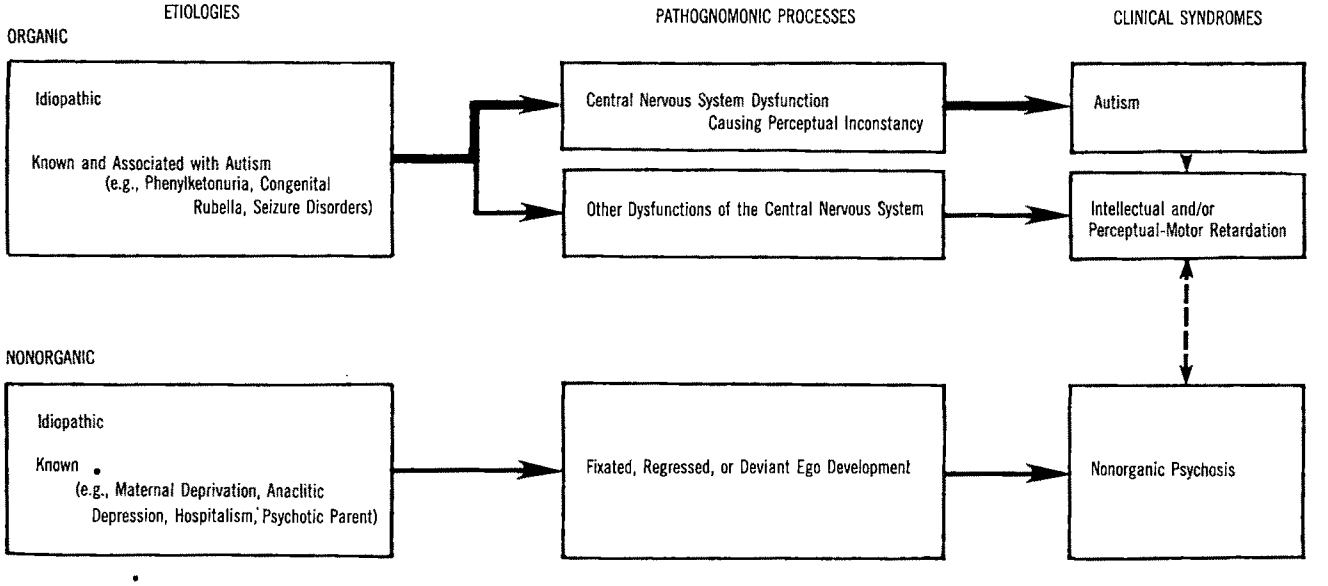
vals. While parental descriptions of the child are necessary, they are clearly not sufficient to establish the diagnosis of autism.

DIFFERENTIAL DIAGNOSIS

For clinical and research purposes, we reserve the diagnosis of autism for patients who clearly show, prior to 36 months of age, irregularities in development and disturbances in the modulation of sensory input, relatedness, and language as described in the previous section. The presence of these symptoms is necessary and sufficient to establish the diagnosis. While motility disturbances are frequently present, they are not necessary to establish the diagnosis. Seventy-six percent of a group of 72 autistic patients we studied had a history of hand-flapping (55).

When reviewing the differential diagnosis, one must consider specific diseases that are known to occur in association with autism. These include phenylketonuria, congenital rubella, other specific organic brain syndromes, mental retardation, and seizure disorders. In addition, one must differentiate diseases with overlapping symptoms, such as environmental deprivation (maternal deprivation and hospitalism), anaclitic depression, developmental aphasia, and sensory deficits. This last category includes syndromes that have been described in the research literature under the rubrics of disintegrative psychosis (56); late onset psychosis (16); acquired autism (57); and childhood schizophrenia, nonorganic type (26).

Figure 1 shows the possible etiological and phenomenological interrelationships among the clinically and behaviorally defined syndromes of autism, primary cognitive and intellectual retardation, and psychologically induced psychosis (severe ego pathology). This model is based on the hypothesis that the syndrome of autism results from CNS pathology of a specific type. This neuropathophysiology may occur on an idiopathic basis or in conjunction with specific diseases of known etiology that affect the CNS. The same neuropathophysiological process underlying autism may also produce cognitive and intellectual retardation and disrupt ego development, producing secondary psychosis. According to this model, primary ego pathology (psychosis) can produce cognitive and intellectual retardation and vice versa, but neither of these alone can "cause" autism.



Idiopathic CNS Dysfunction

This is the category in which most young autistic children have to be placed. However, as an individual patient grows older, there is an increasing likelihood that evidence of specific CNS pathology will become manifest by the onset of specific signs or symptoms (e.g., seizures), and the designation "idiopathic" will be revised (58).

Major Sensory Deficits

Specific sense organ pathology can precipitate severe emotional reactions and developmental arrests in infants and young children. The combination of sensory deficits and secondary ego disturbances may result in a clinical picture that can be confused with autism (59). Therefore, since disturbances of language are part of the syndrome of autism, specific otological and audiological examinations should be carried out (60). Complete or partial blindness is often accompanied by "blindisms" (61). These mannerisms, which

FIGURE 1
A Model of the Possible Etiological and Phenomenological Interrelationships Among Autism, Primary Cognitive and Intellectual Retardation, and Psychologically Induced Psychosis

include gesturing with the arms and hands, do not have the repetitive stereotyped characteristics of the hand-flapping seen in autistic patients, and they occur in response to environmental stimuli. Furthermore, blind children usually develop an interest in their environment and do not have disturbances in relating typical of autism. When their visual deficit is recognized and if other CNS pathology does not interfere, they can develop quite normally. It is of interest that autism has been reported in association with retrolental fibroplasia but not with other types of visual impairment (61). Since retrolental fibroplasia is associated with generalized brain damage, autism in these cases probably results from the CNS impairment and not from the visual deficit per se.

Developmental Aphasia

Both developmental aphasia (27) and autism are accompanied by abnormal responses to sounds, delay in the acquisition of language, and difficulties in articulation (62). Due to their difficulties with expressive and/or receptive language, aphasic individuals may develop secondary disturbances in relating and social responsiveness. They do not, however, manifest the perceptual disturbances (sensory hyperreactivity and hyporeactivity) characteristic of autistics. They can relate by nonverbal gestures and expressions, are sensitive to the gestures and expressions of others, and can learn to point toward desired objects (63). When they do acquire speech, it does not show the lack of "communicative intent and emotion" (64) and delayed echolalia (65) characteristic of autism. Thus the language disability of speaking autistic children is more severe and more deviant than that of aphasic children (66).

Cognitive and Intellectual Arrests and Delays

Clinical experience with autistics and follow-up studies demonstrate that low scores on developmental tests or reports of "untestability" during the early years are associated with retarded intellectual functioning later in life (11, 12). Most autistic individuals cannot perform many IQ test items (43, 67). The notion that autistics have a primary affective deficiency that interferes with the expression of their assumed normal or superior intellectual and cognitive potentials has given way to the recognition that their intellectual deficiencies are every bit as real as those of patients with primary retardation. Accumulating clinical evidence indicates that two-thirds to three-fourths of all autistic patients will perform throughout life at retarded levels (58). Thus mental retardation and autism can clearly coexist (68).

Specific Organic Brain Syndromes

Some children with autism also show evidence of specific organic brain syndromes. Attempts to link autism with Schilder's disease and Heller's syndrome (69) have not been successful since the natural history and clinical course of these degenerative diseases are different. Autism has been reported *in association with* prenatal and perinatal complications (70), neonatal conditions associated with brain damage (e.g., retrolental fibroplasia) (61), infantile spasms (14, 16, 71), cerebral lipoidosis (14), metabolic diseases (e.g., phenylketonuria) (27, 48), Addison's disease (72), celiac disease (73), and infectious diseases (e.g., congenital rubella) (74). An extensive study of a series of patients with rubella revealed that 8% to 10% had specific symptoms indicative of autism (75). Conversely, a number of patients first diagnosed as autistic were shown to have had congenital rubella (74).

Seizure Disorders

Alterations in consciousness and behaviors due to epileptic seizures must be distinguished from autism, particularly since momentary posturing and bursts of hand-flapping, frequently seen in autism, may be confusing. Autism and seizures frequently coexist (14, 16), and it has been demonstrated that two EEGs with sleep tracings are required to evaluate this possibility (76). Seizure disorders are more likely to become clinically manifest in autistic children as they become older. Twenty-five percent of a well-followed series of autistic children first developed seizures between 11 and 19 years of age. Most of these children had had normal EEGs and neurological examinations earlier in life (11, 63). Both grand mal (16, 63) and psychomotor seizures have been observed in autistic children (77).

Maternal Deprivation

It has been suggested that deficient human stimulation, e.g., maternal deprivation, may cause autism (78). The immediate and long-term sequelae of environmental deprivation in infants raised in institutions (79) and at home (80) have been well documented. While environmental deprivation has been shown to induce serious developmental disturbances, it does not produce the syndrome of autism.

Deprived patients characteristically exhibit a uniform delay in the acquisition of motor skills, speech, and the adaptive use of toys. In contrast, autistic children show uneven motor and speech development characterized by spurts and lags. Deprived infants may show unusual bursts of motor activity such as athetoid-type movement of the hands. However, these are not like the repetitive hand-flapping and other motility disturbances seen in autistic children. In addition, the whirling, toe-walking, darting, and lunging movements of autistics have not been observed in deprived patients. These patients do, however, engage in total body-rocking and hand-posturing. These behaviors are easy to interrupt or totally eliminate, in contrast to the more intractable motility disturbances in autistic children.

Deprived patients may also show abnormal patterns of relating and may adapt poorly to being held. They may flick at toys, drop them, or fail to develop an interest in them. In contrast, autistic patients usually use toys in peculiar ways such as spinning, feeling, or

sighting along them. Deprived patients usually fail to seek out adults when given the opportunity. Unlike autistic children, who do not appear to value eye contact, deprived children may intensely engage in visual contact with adults. While autistic patients rarely develop an active interest in playing games with others, deprived children do, although their interest develops later than in normal children. Similarly, their language development may be delayed, but they usually catch up when their deprivation is relieved. Once speech has been acquired, it does not have the atonal, arrhythmic, hollow-sounding quality of autistic speech. Echolalia and misuse of pronouns has not been reported in deprived children, nor have perceptual disturbances indicative of faulty modulation of sensory input. While autistic patients engage in tactile exploration, deprived patients show diminished tendencies to touch themselves and to put objects in their mouths.

A difficult problem in differential diagnosis occurs if a mother has had a postpartum depression or other serious emotional disorder during her child's first year. If an adequate surrogate was not present, the child may have developed an environmental deprivation syndrome. On the other hand, the ill mother might have given birth to an autistic child whose inability to positively relate and respond aggravated preexisting disturbances in the mother.

Anaclitic Depression

Anaclitic depression develops after the sixth month when there is an interruption in a previously adequate mother-infant relationship (81). The interruption may be due to death, psychological withdrawal, or temporary absence of the mother. Such infants become weepy, demanding, and clinging. If the mothering person does not return within a few weeks, this stage may presage psychomotor retardation, delay in development of language, weight loss, and persistent crying. After 2 or 3 months, these signs are replaced by quiet whimpering, facial rigidity, and finally lethargy and apathy. Symptoms of perceptual disturbances, developmental spurts and lags, and disturbances in language and motility characteristic of autism are not seen in children with anaclitic depression. Their failure to relate to adults is characterized by apathy and withdrawal.

Relationship of Childhood Schizophrenia to Autism

The diagnosis of childhood schizophrenia has been applied to a wide spectrum of patients. These range from autistics, as defined in this review, to children without severe developmental or intellectual disabilities but who have psychotic level ego functions. Clinical subtypes have been defined by Bender and associates (10, 21, 82–84) (pseudoretarded or autistic, pseudoneurotic, pseudopsychopathic), Fish (41) (according to language and intellectual development), and Goldfarb (26) (organic, nonorganic). Their use of the term implies that there is a continuum of schizophrenic illness from the prenatal period (maturational lag at the embryonic level, according to Bender and associates) to adulthood, with different ages of onset (onset of autism, prior to 3 years; onset of childhood schizophrenia, 3 years to adolescence; and onset of adult schizophrenia, adolescence or later).

In contrast, Rutter (56) has suggested that the term "childhood schizophrenia" is confusing and should be abandoned. In his view, any patient, regardless of age, whose clinical picture fits the classic description of schizophrenia should be so labeled. He considers autism a separate disease that is first manifested during the first 3 years of life. Once established, it should then remain the primary diagnosis regardless of increasing age and any change in symptoms. He also identified a separate group of children in whom psychotic ego development occurs between the ages of 3 and 5 after an apparently normal course of development and labeled these rare cases "disintegrative psychosis."

In support of the position that there is a continuum of one disease process that includes autism and childhood schizophrenia are clinical reports that when some typically autistic preschoolers reach ages 8 to 12, their clinical picture has changed to fit the criteria of childhood schizophrenia (28). In addition, there are reports of typically autistic children who, as adults, exhibit clinical signs of schizophrenia (82–84) and of some adult schizophrenics whose histories indicate they were typically autistic when preschoolers (85).

We have been able to observe several such cases. One boy, at 4 years of age, clearly met our criteria for autism (developmental delays and disturbances in the modulation of perception, relatedness, language, and motility). He was seen again at age 9 and asked why he rocked and put his hands up before his face. He said, "The floor is coming up at me" and "The walls are moving in on me." Another bright, verbal boy had a similarly documented early history of autism. At age 9, when asked why he flapped his hands before his face, he said, "I am pushing the thoughts back in my mouth." When he was younger, his motility disturbances had included hand-flapping. He was obviously trying to consciously explain, albeit on a psychotic level, the persistence of this symptom.

In support of the alternative hypothesis, namely that autism and childhood schizophrenia are distinct syndromes and should be carefully distinguished, Rutter (56) detailed the following differences: 1) familial factors (absent in autism but present in schizophrenia), 2) ages of onset, 3) symptoms, and 4) natural history and course of the disease.

For heuristic purposes, we are exploring theoretically and in the laboratory the possible neuropathophysiological processes that may produce the symptoms common to both schizophrenia and childhood autism, whether they are the same syndrome or not (29, 30). It is incumbent upon each physician to understand both the descriptive elements of the two terms and that these nosological differences have more than just semantic meaning. Indeed, they have marked implications for total patient management and for the

application of specific supportive treatments. For example, developmentally retarded autistic patients with severe language disturbances, as described in this review, respond best to a combination of behavior therapy and special education (86). On the other hand, the thought and affective disorders typical of childhood schizophrenia respond best to a combination of psychotropic medication, psychotherapy, and milieu therapy (87).

CLINICAL RESEARCH

Prenatal and Perinatal Factors

Several studies have shown that premature birth is not significantly associated with autism (16, 88, 89). Other reports have shown that certain prenatal and perinatal complications are more common in autistic individuals than in control groups (16, 70, 88–90). When all prenatal and perinatal complications are considered, there is a suggestion that they may be significantly associated with autism (16, 70). These findings must be viewed with caution due to the lack of uniformity in both the diagnostic criteria for autism and in the selection of prenatal and perinatal complications by the investigators.

Constitutional and Genetic Factors

With the exception of two studies (91, 92), neither an increased incidence of schizophrenia nor a history of autism has been reported in the parents or nontwin siblings of autistic children (16, 18, 20, 93). Twin studies have suggested that monozygotic pairs are likely to be concordant for and dizygotic pairs discordant for autism.[1] It is of particular interest to note that autism occurs in diverse racial populations and in all parts of the world.

Attempts to find chromosomal abnormalities in autistic patients have been unsuccessful (94). Studies reporting unusual dermatographic patterns (95) and hand morphology (96) in some "psychotic children" with "autistic features" have yet to be replicated.

Family Characteristics

The old notion that parents of autistic children are highly intelligent, preoccupied with abstractions, have limited interest in people, and are emotionally "cold or refrigerated" (45) is not supported by recent research (16, 63, 97). In addition, the concepts of unconscious parental hostility and rejection (98), parental "perplexity" (99), and lack of communicative clarity (100) do not apply to the parents of autistic children.

Controlled studies have shown that the extreme emotional stress of having an autistic child can induce or precipitate emotional disorders in susceptible parents (91). Furthermore, the physician's assumption that there is something wrong with the parents which causes autism may produce a iatrogenic emotional disorder in the parents (101). The possibility of disturbances in family dynamics at an early critical period has also been suggested as etiological (5–7). However, no objective evidence has been presented to support this hypothesis, and other studies have found normal family structure concurrent with autism (102).

Since Kanner first described the syndrome in 1943 (3), several reports have suggested that parents of autistic children are of above-average intelligence (27, 45, 88, 91, 93). These studies used group tests, which are known to result in higher scores for parents from higher social classes (18). Two well-controlled comparisons of the verbal IQs of mothers and fathers of autistic and normal children matched for socioeconomic status found no significant differences (103, 104). These findings are confirmed by our unpublished data and clinical experience.

Several reports have suggested that families of autistic children have a higher social class distribution than would be expected to occur randomly or when compared with other specific groups of patients (3, 16, 20, 88, 91, 93, 105). These results have *not* been confirmed by three other surveys. The first of these compared the distribution of autistics and "non-autistic psychotics" among five social classes (106). Ritvo and associates (107) compared the families of autistics with those of matched nonautistic patients and the expected distribution based on population data. A third study compared families of autistic patients with those of matched normal subjects (103).

Studies of Prevalence

Lotter (108) found a prevalence of 4.5 autistic children per 10,000 8- to 10-year-olds in Middlesex County, England. Treffert (105) found a prevalence of 0.7 per 10,000 in the state of Wisconsin. He surveyed children aged 3 to 11 and used different epidemiological techniques and possibly different diagnostic criteria than Lotter. Both prevalence figures can be considered low since autistic children younger than 4 and older than 6 are often misdiagnosed. In any event, autism is not so rare a condition as was once thought, and it represents a significant social problem.

Studies of Prognosis

Between 7% (14) and 28% (58) of autistic children who have shown no clinical evidence of neurological disease in early childhood develop seizures by age 18. Approximately 75% of all autistics are classified as mentally retarded throughout life (15, 58). Those who have seizures and other indications of specific organic brain dysfunction also tend to be the most retarded, underdeveloped, and impaired (58). Failure to develop communicative language by age 5 is also highly correlated with poor prognosis for further personality development (11, 15, 24, 45). Failure to develop the capacity to use toys appropriately is also associated with a poor prognosis (109). Thus the 5-year-old autistic child who does not have communicative language, i.e., remains mute or solely echolalic, does not play appropri-

[1]For a review of this subject see reference 52.

ately with toys, and has severe cognitive deficits has the poorest prognosis. Autistic children with low IQs show the poorest response to treatment (110); these patients will most likely require lifelong, 24-hour care.

The minority of autistic children who show relatively normal intellectual, cognitive, and motor development and have communicative language before age 5 have a somewhat different prognosis. Clinical experience indicates that most of these patients do not develop a thought disorder with delusions and hallucinations (58). However, most of the patients in this group become extremely shy, introverted, and passive adolescents. Some develop disturbances in reality testing typical of pseudoneurotic childhood schizophrenia or the borderline state (9, 15, 21). A study of one series of cases (13, 28) and several individual case reports document transitions from typical autism to typical schizophrenia in late childhood (2), adolescence (29), and adulthood (82–85). As previously noted, follow-up studies of the relationship between early autism and later schizophrenia deserve consideration (29, 30).

Although it has been reported that some autistic adults are able to live alone and obtain employment, we must emphasize that they represent a small minority of cases. Even those with the best combination of good prognostic factors will probably have significant residual personality and cognitive impairments in adolescence and adulthood (13). Thus even those exceptional patients who show significant improvement during childhood remain aloof and literal and lack social judgment and empathy (111).

Neurological and EEG Studies

The findings from neurological examinations of most autistic children are unremarkable (112). However, "soft" neurological signs such as poor muscle tone, poor coordination, clumsiness, hyperactive knee jerks, hypotonia, generalized hyperreflexia, drooling, short attention span, hyperkinesis, hypokinesis, ankle clonus, and strabismus have been reported in 40% to 75% of several series of patients (26, 89).

EEG findings are quite variable. Two reports of unusually low voltage EEGs suggestive of hyperarousal (16, 49) were not confirmed in two other studies (113, 114) when stimulus conditions were controlled. While some researchers have reported that 50% to 80% of autistic patients have abnormal EEGs characterized by focal or diffused spike, slow wave or paroxysmal spike and wave patterns (89, 113, 115), others have reported a lower incidence of EEG abnormalities (16, 112).

NEUROPHYSIOLOGICAL RESEARCH

Because of the usual extreme lack of cooperation by autistic children, neurophysiological studies have been quite limited in scope and number. Autistic children have a normal sleep cycle with normal amounts of rapid eye movement (REM) sleep (116). However, the REM activity of REM sleep is reduced in autistic children and is similar to that found in normal infants, suggesting a maturational defect (117). While the transcephalic direct current potential is similar in autistic and normal children, an unusually high percentage of DC bursts have been found in 6- to 13-year-old autistic children and 1- to 5-year-old normal children (73). Unfortunately, that study did not have adequate controls for eye movement activity, so this interesting maturational finding may only reflect the tendency of older autistic and younger normal children to have more vertical eye movements.

The contingent negative variation (CNV) is intact in autistic children when two stimuli are paired together, but the autistics, unlike normal controls, do not show a differential response to slides of familiar and strange faces (118). This does not seem to represent a neurophysiological abnormality since the basic ability to establish a CNV is intact; rather, it reflects the ordinary clinical experience that autistic children do not show adequate differential responses to strangers and do not participate in social interaction.

Studies of auditory evoked responses (AER) during sleep have revealed only marginal differences between autistic children and controls and have been characterized by great variability from subject to subject (119). Studies of the recovery cycle of the AER during sleep have also demonstrated normal responses in autistic children (120). One study of evoked responses to flashes and clicks in waking autistic children was inconclusive since no statistical analysis of the data was presented (121). An inadequate galvanic skin response to both auditory and visual stimuli has been demonstrated in autistic children (122). This finding is consistent with the clinical observation that autistic children do not show an adequate startle response. It was not possible, however, to replicate the finding by using changes in heart rate as the experimental measure (123). Increased variability in the heart rate has been reported, but adequate control of the activity level and stimulus conditions under which autistic and normal children were observed was not documented (124). Thus this assertion that evidence was found for brain stem dysfunction is somewhat tenuous.

However, other evidence implicating a brain stem disturbance has been found. Three separate studies have demonstrated a consistent suppression of vestibular nystagmus in autistic children (125–127). Ornitz and associates (128) have demonstrated that this finding is not dependent on visual fixation but rather reflects a pathophysiological interaction of the visual and vestibular systems. It has also been found that vestibular stimulation does not influence the REMs of REM sleep in autistics as it does in normals (53). Ornitz (129) has discussed the possible significance of these investigations for a theory of brain stem dysfunction involving the central connections of the vestibular system. He also suggested that there may be a strong motor component to the perceptual processes of autis-

tic children (129). This notion is supported by a report that slow waves (in AERs) provoked by movement appeared in autistic children during sensorial conditioning that required no movement (130).

METABOLIC, BIOCHEMICAL, AND HEMATOLOGICAL RESEARCH[2]

There have been several studies of indoleamine metabolism in autistic patients. Although the results were preliminary and inconsistent, they suggest that this field of investigation requires further serious study. One study (131) demonstrated decreased urinary excretion of 5-hydroxyindoleacetic acid in response to a tryptophan load, but this finding was not replicated in a later study (132). Heeley and Roberts (133) observed the effect of tryptophan loading and reported results that suggested abnormal function of the kynurenine pathway. Sankar and associates (134) found increased amounts of indolic substances in the urine of 5- to 16-year-old hospitalized "schizophrenic" patients. However, they did not provide sufficient clinical information to determine whether these children could be considered autistic as described in this review. In contrast to the findings of Sankar and associates, Jorgensen and associates (135) observed a significant reduction in the urinary excretion of tryptophan in 3- to 6-year-old "psychotic children." Another study (136) reported the presence of bufotenin (N,N-dimethylserotonin) in the urine of some autistic subjects; the significance of this finding is still uncertain.

Another group of studies has focused on the level of serotonin in peripheral blood, where it is transported in platelets. In 1961 Schain and Freedman (137) reported that 25% of a group of 23 institutionalized patients diagnosed as autistic had elevated blood serotonin levels. Ritvo and associates (138) found a significantly higher amount of whole blood serotonin in five autistic children 36 to 47 months of age than in seven age-matched normal children but no significant difference between older autistics and their age-matched controls. They also noted that platelet counts decreased in normal children aged 2–8 years and increased in autistic children through that age range; however, these differences did not reach statistical significance. Yuwiler and associates (139) were unable to explain these results on the basis of differences between autistic and nonautistic children in circadian rhythmicity for either whole blood serotonin or platelets.

Ritvo and associates (140) also studied the effect of prolonged (6-month) administration of L-dopa on autistic children. Blood serotonin levels decreased in three out of four autistics and platelet counts tended to increase. However, no change was rated in the clinical course of these patients or in their sleep patterns while they were receiving L-dopa. Zarcone and associates (141) reported that chronic oral ingestion of the serotonin precursor 5-hydroxytryptophan had no effect on the behavior of two autistic children. However, it did cause an increase in REM sleep time and in the number of REMs during REM sleep, an effect that also occurs in normal subjects.

A group of related investigations into the transport of serotonin by blood platelets has been conducted. Sankar and associates (134) found that the in vitro rate of uptake of serotonin by platelets was less in "schizophrenic" children than in a control group of hospitalized patients. Boullin and associates (142) reported an increased efflux of serotonin from the platelets of patients diagnosed as autistic by the Rimland E-2 questionnaire. They did not find any unusual differences in uptake or loss of dopamine from the platelets of autistics similarly diagnosed. We have been unable to replicate findings of different uptake and efflux rates between autistics and carefully matched control subjects despite our use of similar and improved methods (143, 144).

A number of other biomedical measures have been reported. The plasma cortisol level, eosinophile count, and histamine wheal test do not reveal remarkable findings in autistics. Plasma and erythrocyte cholinesterase activity, serum magnesium, copper ceruloplasmin, and ascorbic acid levels are normal in autistic patients. Baseline free fatty acid levels and plasma free fatty acid response to glucose ingestion are also reported to be within normal limits, except for increased variability in the baseline plasma free fatty acid level. These may be associated with greater variability of daily caloric intake. In one study (145), plasma and red blood cell inorganic phosphate were found to be elevated in autistic subjects. One report (146) described pituitary hypofunction (reduced secretion of the gonadotropins adrenocorticotropin and follicle-stimulating hormone) in psychotic patients with the onset of illness in the first 3 years and behavior suggesting autism; this study should be replicated.

A study of smears of peripheral blood from "schizophrenic children" (147) showed an atypical leukocyte pattern. These abnormalities were similar to those associated with increased antibody production, responses to viral infection, and allergic sensitivity. They could not be distinguished from those found in blood smears of children with colds or asthma. These results may thus reflect the presence of an infectious disorder. Preliminary reports from one laboratory (148) on a serum factor that increases the susceptibility of mice to seizures deserve further investigation in view of the increased incidence of seizures with increased age in autistics (14, 58).

MEDICAL MANAGEMENT AND TREATMENT

We must emphasize that there is no rational or specific treatment for autism. In spite of strong claims by partisans of particular treatment approaches and much

[2]A more complete list of references to these studies appears in the review by Ornitz (52).

dedicated effort that has gone into their implementation, no treatment has been demonstrated to alter the natural history of the disease (149). Many different approaches have been attempted including family therapy, psychotherapy and counseling for parents, psychotherapy for the autistic child, behavior therapy, speech therapy, and special education. Therapeutic approaches also include day treatment, residential treatment, psychiatric hospitalization, medication with a number of different psychotropic drugs, hormones, megavitamins, electroconvulsive therapy, sensory stimulation, sensory isolation, and even LSD. The literature on these various treatment approaches and the application of the different treatment modalities has been critically reviewed elsewhere (52, 150).

A recent review by Campbell (151) confirmed our clinical experience that psychotropic medications do not alter the natural history or course of autism. However, they are useful adjuncts to treatment on a symptomatic level. The target symptoms amenable to medication (e.g., hyperactivity, aggressiveness, and sleep disorders) are not specific to autism. Furthermore, we also concur with Campbell that excessive sedation often results when therapeutic levels of psychotropic medication are reached. This unwanted side effect can reduce the patient's participation in other therapeutic programs (e.g., educational ones). Thus we reserve the use of psychotropic medications for those cases where behavioral-based therapies alone have proven ineffective.

Since autistic patients vary greatly in their intellectual and cognitive capacities, use and understanding of language, general developmental level, age at the time symptomatic treatment is instituted, level of ego development, and family circumstances, it is not surprising that some treatment approaches have ameliorated symptoms in certain cases but not in others. Response to a symptomatic treatment is determined primarily by the degree of impairment and secondarily by the type of treatment (109). Thus, although autistics may improve in specific respects, they remain definitely autistic.

We (52, 150) and others advocate early recognition, continued medical supervision, and a flexible approach to treatment. Periodic reevaluations are necessary to adapt supportive treatments to changes in developmental level and symptoms (151). Parents should be viewed as paraprofessionals who frequently can best implement symptomatic treatments such as behavior therapy. Patience is the hallmark of management, and one must recognize that spontaneous improvements and regressions are likely to occur despite the influence of the most optimistically presented symptomatic treatment plans.

CONCLUSIONS

Ontogeny recapitulates phylogeny in the history of diseases as well as man. Thus, since its conception a scant 30 years ago, autism has undergone many vicissitudes. It was conceived as an adjective ("autistic disturbances of affective contact"), relegated to symptom status ("mental retardation with 'autistic features' "), made a stepchild of a stepchild ("childhood schizophrenia, autistic type"), and finally emerged as a noun (the syndrome "autism").

In this review we have tried to survey those studies which were based upon serious scientific efforts and avoid those which simply expressed opinions. The current state of our medical art leads us to the following conclusions.

1. Autism is a clinically and behaviorally defined specific syndrome.
2. It is manifested at birth or shortly thereafter and remains throughout the lifetime of the patient.
3. Its symptoms are expressive of an underlying neuropathophysiological process that affects developmental rate, the modulation of perception (sensorimotor integration), language, cognitive and intellectual development, and the ability to relate.
4. No known factors in the psychological environment of a child can cause autism.
5. To establish the diagnosis it must be demonstrated that before the age of 36 months the patient had specific disturbances in developmental rate, perception, relatedness, and language. Many, but not all, patients demonstrate typical motility disturbances.
6. Autism occurs on an idiopathic basis or in conjunction with other diseases that affect the CNS.
7. It afflicts children in all parts of the world, of all racial and ethnic backgrounds, and is found in families with the normally expected distributions of intelligence, social class, and personality factors.
8. No etiologically based rational treatment is available that alters the course of the disease.
9. Complete medical and neurological evaluations are essential to establish the diagnosis, and they should be repeated at yearly intervals. Particular attention should be paid to the likelihood that seizure disorders may appear in individual patients as they grow older.
10. Supportive and symptomatic therapeutic measures (e.g., behavior therapy, special education, and residential treatment) are helpful in most cases. These should be monitored by a physician-in-charge and administered by specialists and parents trained in these modalities. Periodic reevaluations and updating of supportive therapeutic programs are necessary to keep abreast of the clinical changes that can be expected to occur in the majority of cases.
11. The long-term prognosis, unfortunately, is guarded. Approximately two-thirds of all patients manifest intellectual and cognitive deficits severe enough that they remain classified as retarded throughout their lives.
12. Further basic research into the neuropathophysiological process underlying the syndrome is necessary if we are to develop a rational treatment program, which is the ultimate goal of our efforts.

EEG Sleep Changes as Predictors in Depression

BY DAVID J. KUPFER, M.D., F. GORDON FOSTER, M.D., LOUIS REICH, M.D., KENNETH S. THOMPSON, AND BRIAN WEISS, M.D.

The authors conducted a study of 18 depressed patients to see whether EEG sleep measurements might provide a predictive tool for response to antidepressant medication. They found that although the sedative characteristics of amitriptyline did not differentiate good responders from poor responders until the third week of drug treatment, the good responders showed significant increases in REM latency, decreases in REM sleep time, decreases in REM sleep percent, and decreases in REM activity after only 2 nights of drug treatment.

THE CORRECT DIFFERENTIAL DIAGNOSIS and appropriate treatment of any psychiatric syndrome are of obvious importance, but they are particularly vital in the treatment of affective disease because therapeutic response may not begin to occur until several weeks after the initiation of treatment (1, 2). Clinicians have known for a long time that the tricyclic antidepressants do not begin to act in the treatment of recurrent depression for at least 10 to 14 days (3, 4). Indeed, it has been argued that a 3-week trial of this medication at therapeutic levels is necessary to assess its effectiveness. Therefore, the development of prognostic criteria for treatment response in affective disease would be extremely helpful to both the practicing clinician and the clinical investigator (5).

Recently there have been several attempts to determine who is likely to respond to tricyclic therapy that have used clinical data and psychobiological measurements obtained in the pretreatment phases of hospitalization (6). Responders to tricyclics might also be determined by monitoring physiological or psychological measurements during the first few days and nights of drug administration. Both of these research strategies imply the applicability of psychobiological measurements in the differential diagnosis and treatment of affective states.

As reported previously (7), EEG sleep measurements can be used as a diagnostic indicator in unipolar and bipolar depression. Investigations have shown that shortened REM latency is a feature of primary depression and, furthermore, that the hypersomnic-hyposomnic determination may help categorize the depression as either bipolar or unipolar (8–10). Even though a more practical nosology of depressive syndromes will probably be based in part on such psychobiological measurements as sleep and motor activity, the development of prognostic indicators aided by psychobiological measurements is of equal importance. With this in mind we decided to study EEG sleep in relation to the administration of tricyclic antidepressants to determine whether treatment response could be predicted on the basis of EEG sleep during the first few nights of drug administration.

This investigation was made easier by the fact that our previous studies have shown that patients do not always need to be studied longitudinally; in fact, one can ascertain the main EEG sleep features with regard to primary depression on the basis of even two nights' study (11). We were therefore able to examine the interaction among clinical changes, drugs, and EEG sleep using a design involving intermittent EEG sleep recording.

METHOD

We studied 18 patients (11 women and 7 men with a mean age of 51.4±2.3 years) who had been admitted to our clinical research unit with the diagnosis of unipolar depression. As in our previous studies, all of the patients had been drug free for a minimum of 2 weeks before the study, were selected on the basis of independent evaluations by at least two attending psychiatrists, and gave informed consent. Clinical diagnoses were made on the basis of the criteria described by Feighner and associates (12). In addition, systematic assessments of behavioral dimensions with emphasis on depressive and psychotic symptoms were obtained by using self-rating and clinical rating scales (13–15).

All of the patients were studied in their rooms on the research service by means of continuous nightly recordings of their EEGs, horizontal electrooculo-

This study was supported in part by grant MH-24652 from the National Institute of Mental Health.

grams (EOGs), and submental electromyograms (EMGs). Their records were evaluated according to the standard criteria (16) by a scorer who was unaware of any patient's clinical status or treatment. In addition to the EEG categorization of sleep stages, each minute of REM sleep was scored on a 9-point scale (0–8) for intensity of REM patterns reflecting both the amplitude and the number of conjugate eye movements (17). Sleep efficiency was measured by using a ratio of minutes of time spent asleep (TSA) to minutes of the total recording period (TRP).

The experimental design required that the 18 patients be studied during three periods: at least 3 consecutive nights before drug administration (baseline), the first 2 nights of drug treatment, and 4 consecutive nights during the third week of drug treatment. During the first 2 nights of drug administration. 7 patients each received orally a total of 150 mg and 11 patients each received a total of 200 mg of amitriptyline. During the third week of treatment the 18 patients were receiving daily therapeutic doses of the drug that ranged from 150 to 250 mg (mean 24-hour-dose, 191±4.7 mg). Amitriptyline was the only medication used in this study; all of the patients were receiving therapeutic doses (at least 150 mg) by the fourth day of treatment.

The sleep characteristics reported here are based on the mean EEG sleep values obtained during each of the three periods of time. A variety of REM measurements (REM time, REM latency, REM activity, cycle lengths) and non-REM measurements (sleep latency, intermittent awakening, early morning awakening, delta sleep, time spent asleep, and sleep efficiency) were examined. For each patient the baseline sleep measurements were compared with those for the first 2 nights of drug treatment and with those for the third week of drug treatment. Student's two-tailed t test for ungrouped data and Pearsonian correlations were the main statistical procedures used in this study.

During the third week of the study a clinical assessment was made that divided the group into patients who had successfully responded to amitriptyline administration and those who had either a poor or a weak response. The basis for this clinical judgment was the Kupfer-Detre System (KDS) clinical ratings for depression (excluding items relating to sleep disorders) (13–15). A change score of 3 or greater was considered the criterion for a positive clinical response. The clinical raters were unaware of the nature of the study being conducted. At the end of the 3-week study period, 7 of the 18 patients had responded unequivocally to amitriptyline. An analysis of the two groups (responders versus nonresponders) indicated no significant differences in terms of age (50.6 years versus 52.0 years), amount of drug received on the first 2 nights (183 mg versus 185 mg), or amount of drug received during the entire 3-week period (186 mg versus 195 mg). In addition, there were no differences in their baseline EEG sleep measurements (see table 1).

RESULTS

In order to analyze the different responses of the two groups of patients, we examined the differences in EEG sleep between the baseline period and the first 2 nights of drug administration (see table 2). On the basis of the measurements obtained on the first and second nights of drug administration, the good clinical response group consisted of patients who showed a marked decrease in REM sleep percent, a marked increase in REM latency (particularly on the first night of drug administration), and decreased REM activity (see table 3). No significant differences in EEG measurements that are usually associated with sleep continuity or any of the other stages of sleep were detected.

* In minutes unless otherwise indicated.
** Ratio of time spent asleep (TSA) to total recording period (TRP).

The changes in REM sleep percent correlated significantly with clinical response ($r=-.69$, $p<.01$), as did REM latency ($r=-.55$, $p<.05$) and REM activity ($r=-.55$, $p<.05$).

For the purposes of prediction, the mean sleep changes for both nights might be most applicable for deriving cutoff scores for new cases. For example, by using a mean cutoff level of 10% REM reduction during the 2 nights, 82% of the patients were placed in the proper groups. If a REM percent reduction of 10% or a REM latency change of greater than 100 minutes is used, the correct identification goes up to 88%.

With respect to the follow-up period (the third week of drug administration), both groups of patients showed marked changes in their EEG sleep in comparison with their baseline levels (see table 4). Although the good responders showed a significant increase in total sleep time (70 minutes, $p<.01$) and in sleep efficiency (17%, $p<.01$) during the follow-up period in comparison with their baseline levels, these patients also had an increase in REM latency of 90 minutes ($p<.01$), which was mirrored in a 10% decrease in REM sleep percent ($p<.01$). On the other hand, although the poor responders also showed a moderate increase in time spent asleep (44 minutes, $p<.05$), they showed a nonsignificant increase in sleep efficiency. The poor responders showed an increase in REM latency of 64 minutes ($p<.05$) as well as a 9% overall decrease in REM sleep percent ($p<.01$).

Regardless of clinical response, there were obvious drug-induced changes in the sleep of both groups. These EEG sleep changes reflected alterations in sleep continuity (more sleep efficiency, $p<.01$; reduced early morning awakening, $p<05$); in increased total recording period, $p<.01$; and in REM sleep (particularly REM latency, $p<.001$; decreased REM sleep percent, $p<.001$; and even a reduction in REM intensity, $p<.001$). At the time of the follow-up period, amitriptyline still exerted a pronounced effect on EEG sleep in both groups, especially in relation to time spent asleep ($p<.01$), prolonged REM latency ($p<.01$), and reduced REM percent ($p<.001$). Interestingly, although REM intensity was restored to normative levels in the good-response group, it was still significantly reduced in the poor-response group at the time of follow-up.

DISCUSSION

Our study and earlier investigations have established a significant and pronounced effect of amitriptyline on the sleep of psychiatric patients, but there have been no investigations that differentiated clinical response on the basis of the effects of the drug on sleep. Indeed, because sleep changes are very often symptoms of affective disorders and sleep changes have sometimes preceded clinical improvement, EEG sleep measurements might represent an objective indicator that would not only aid us in monitoring the course of depressive illness but in fact predict clinical response.

That amitriptyline exerts a significant drug effect on EEG sleep measurements, with respect to both sleep continuity and REM sleep, has been shown (18, 19). Amitriptyline seems to possess a sedative effect in that patients show increased time spent asleep along with less intermittent and early morning wakefulness. Similarly, amitriptyline seems to produce pronounced changes in REM measurements, e.g., increases in REM latency and decreases in REM percent, REM time, and even the intensity of REM sleep.

Despite the acknowledged sedative properties of the drug, the good responders in our study could not be differentiated from the poor responders on the basis of sedation (increased sleep time and increased sleep efficiency). These characteristics, which have been reported as an early drug effect, did not separate good from poor clinical responders until the 3-week follow-up period. This unexpected finding suggests that the

extent of sedation may not predict eventual clinical response, at least not when sedation is defined as an increase in sleep continuity. If sedation is defined in terms of the patient's perception of sedation (which includes a manifestation of a general sense of restlessness and may be reflective of REM sleep alterations), it may be that what the patient reports as a sedative effect represents a clinical lead on which to base a differentiation of good responders from poor responders.

This preliminary investigation would seem to indicate that the REM sleep changes in the good clinical responders compared with the poor responders were more intensive and pronounced than can be explained on the basis of drug effect. That is to say, although REM latency was increased significantly in both responders and nonresponders, it was significantly more increased in the good responders. Similarly, REM sleep percent reduction was significantly more pronounced in the good-response group as contrasted to the poor-response group. The significance of the REM suppression that occurs within the first 2 days of drug administration and its persistence over a period of weeks are still relatively unknown (18).

The immediate REM suppression after administration of tricyclic antidepressants is somewhat similar to the report that the administration of amphetamine, which can cause a marked REM suppression without any associated sedative effect, may produce at least a partial clinical remission after only 1 night (20). This investigation (20) also indicated that response to dextroamphetamine may be a possible predictor of improvement with tricyclic treatment of depression. Other investigators (21–23) have suggested this kind of differential prediction in relation to amphetamine, MHPG levels, and treatment outcome. The possible use of REM sleep changes as predictors of drug response also bears a strong relationship to recent studies suggesting that prolonged REM deprivation may be a treatment technique for endogenous depression (24).

The differential response of the good responders and the poor responders in terms of REM suppression was transient; several weeks later both treatment groups were experiencing a similar degree of REM suppression (9% to 10% REM sleep reduction, compared with baseline levels). On the basis of the REM deprivation idea, one would expect that both groups would have had a similar clinical response. However, our patients were not monitored continuously; the true extent of the cumulative REM deprivation as manifested in decreased REM sleep and prolonged REM latency is therefore not known. Such a study requires a longitudinal approach. One might speculate that at least 7 to 10 nights of a sustained elevation of REM latency of 200 minutes or greater and less than 10% REM sleep are necessary to achieve a clinical remission.

With regard to future strategies using this kind of approach, it may be that a more systematic evaluation can be devised if an intramuscular injection of amitriptyline or a test dose of 150 mg at bedtime is administered in a single night trial. This technique might be contraindicated in older patients unless a 100-mg dose is used. The monitoring of blood levels of amitriptyline would be extremely helpful to determine whether the initial blood levels achieved in the first 24–48 hours are predictive of clinical response. In addition, as we reported previously (25), the telemetric monitoring of motor activity may add a further measurement technique to this type of investigation.

The advantages of such psychobiological techniques are apparent. If EEG sleep changes or other psychobiological measurements could be used early in the course of treatment of depression to predict clinical response to tricyclic therapy, at least three major benefits to the patient would result: the incidence and duration of hospitalization would be reduced, his suffering could be diminished, and his work and social functioning could be preserved. In addition, the cost/benefit ratio of treating inpatients for endogenous depressive disorders with tricyclic therapy could be reduced tremendously if such a predictive tool could be applied successfully. This strategy may also prove to be of great relevance in the outpatient treatment of affective disorders. Because the majority of affective episodes are treated on an outpatient basis, this would be extremely useful.

Cocaine, Kindling, and Psychosis

BY ROBERT M. POST, M.D., AND RICHARD T. KOPANDA, M.A.

The authors review the evidence indicating that repetitive administration of central nervous system stimulants and other compounds may be associated with progressively increasing effects on pathological behavior and seizures rather than tolerance. They suggest that the progressive effects of these compounds may be related to electrical kindling, a phenomenon in which repetitive subthreshold stimulation of the limbic system is eventually associated with major motor seizures. They review the studies supporting a pharmacological kindling mechanism and suggest a kindling model for psychological stimuli that combines neurophysiological, biochemical, and psychological perspectives.

IN AN EARLIER PAPER (1) it was suggested that the effects of cocaine and related stimulants in man may progress from the predominantly affective to the schizophreniform spectrum with increased duration of administration. Clinical work with depressed patients and addict volunteers (2, 3) indicated that although cocaine is capable of producing mood elevation in some patients, it may be associated with dysphoric effects when administered intravenously in high doses. These data, in combination with the clinical reports that chronic administration of cocaine or amphetamine can produce a psychosis resembling paranoid schizophrenia (4–10), suggest that an identifiable mechanism might be involved in the progression from the initial euphoric-dysphoric effects to the psychotogenetic.

The evolution of these clinical syndromes may be related to the finding that repetitive administration of the same dose of cocaine or amphetamine to animals produces increasing effects on some aspects of behavior. We will discuss the evidence and some possible mechanisms for these progressive changes (reverse tolerance), including a pharmacological kindling of the limbic system (11, 12). Kindling describes the phenomenon in which repetitive subthreshold electrical stimulation of the limbic system produces increasing effects on electrical activity and behavior, eventually resulting in major motor convulsions in reaction to a stimulation that previously produced no effect (13–16).

Kindling has been used as a model for neuronal plasticity and epileptogenesis, but it has not been directly related to pharmacological or behavioral phenomena. A kindling model for increased behavioral effects of repetitive electrical or pharmacological stimulation over time may provide an important explanatory concept for the progressive development of some psychopathological behavior in man. We postulate that repetitive psychological stresses may also be capable of activating critical limbic system mechanisms involved in the modulation of emotional and cognitive behavior in a progressive or kindling-like fashion.

REVERSE TOLERANCE EFFECTS

The studies supporting the concept that repetitive stimulant administration can be associated with progressive alterations in behavior are summarized in table 1. Tatum and Seevers (17) and Downs and Eddy (18, 19) reported that repetitive administration of cocaine to dogs and rats was associated with increasing excitability and susceptibility to cocaine-induced convulsions. Similar findings have been reported by other investigators in other animals (20–23). Likewise, repetitive administration of amphetamines, which are generally similar to cocaine pharmacologically and behaviorally (32–35), has been associated with increasing effects on activity (27, 28), stereotypy (25–29), and disruption of learned behavior (30).

The intriguing possibility that patients might react to stimulant administration with increased sensitivity over time has been set forth by Kramer (31), who suggested that amphetamine addicts may experience an almost immediate reactivation of paranoid ideation when they take amphetamine, even after a prolonged period of abstinence.

The review in table 1 is not inclusive; only studies demonstrating that chronic amphetamine or cocaine administration could be associated with reverse tolerance effects were selected; the many studies demonstrating no change in behavior or tolerance (32–36) were purposely omitted. The schedule of drug administration, the dose levels, and the parameter studied (32, 37) may be critical determinants of whether tolerance or reverse tolerance effects are manifest.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

TABLE 1
Selected Studies Supporting Progressive Behavioral Effects of Repetitive Stimulant Administration

Study	Drug	Animal Tested	Effect
Tatum and Seevers (17)	Cocaine	Monkey, dog	Excitement, activity
Downs and Eddy (18)	Cocaine	Rat	Seizures, death
Downs and Eddy (19)	Cocaine	Dog	Excitement
Gutierrez-Noriega and Zapata-Ortiz (20)	Cocaine	Dog	Hyperthermia, seizures, death
Gutierrez-Noriega (21)	Cocaine	Dog	Catalepsy
Post (22); Stripling and Ellinwood (23); Ho (24)	Cocaine	Rat	Stereotypy
Post and Kopanda (11); Post and associates (25)	Cocaine	Monkey	Abnormal visual searching, catalepsy, seizures
Mago (26); Segal and Mandell (27)	Amphetamine	Rat	Stereotypy, hyperactivity
Klawans and Margolin (28)	Amphetamine	Guinea pig	Stereotypy, dyskinesias
Ellinwood and Kilbey (29)	Amphetamine	Monkey	Stereotypy, dyskinesias
Ranje and Ungerstedt (30)	Amphetamine	Rat	Disruption of learning
Kramer (31)*	Amphetamine	Man	Reactivation of paranoia

*This report provided data suggestive of an increased reactivity to amphetamine following previous abuse of the drug.

Recent data from our laboratory (25) suggested that repetitive daily administration of the same dose of cocaine to rhesus monkeys produces an increase in a variety of abnormal behaviors as well as an increased susceptibility to convulsions. After an initial phase during which most of the animals showed prominent hyperactive and stereotypic behavior in response to cocaine administration, they showed an increasing severity of motor inhibition, catalepsy, and abnormal visual behavior, including staring and apparent tracking of nonexistent objects about the laboratory. Moreover, animals that did not have convulsions following the initial injections developed increasingly frequent seizures following later injections. Cocaine-induced dyskinesias also developed with progressive severity in some animals treated for more than 10 weeks. The inhibitory syndrome and late dyskinesias appeared to be very similar to the reactions of the monkeys described by Ellinwood and associates (29, 38) following chronic, increasing doses of amphetamine.

Since both cocaine and amphetamine strongly potentiate catecholamines at the synapse (36, 39) by blocking the reuptake of catecholamines or increasing their release, it is tempting to relate the progressive effects of these drugs over time to their effects on neurotransmitter amines. In order to further clarify the role of cocaine's local anesthetic effects versus its amine-potentiating effects in producing the progressive behavioral syndromes over time, we investigated lidocaine, a compound with equal local anesthetic potency but no known amine potentiation at physiological doses (12). Like cocaine (40), lidocaine produces prominent spindle, seizure, and after-discharge activity in limbic system structures when administered in relatively high doses (41–43).

In a study reported in detail elsewhere (12), high doses of lidocaine (60 mg/kg) were administered intraperitoneally once daily to Sprague-Dawley rats. In contrast to the results we saw with cocaine (22), hyperactivity and stereotypy were not observed; rather, the animals engaged in a variety of abnormal eating behaviors (omniphagia and coprophagia). Although none of the control rats ate straw or feces, after 8 weeks of lidocaine administration more than 60% of the rats given the drug consistently ate these and other foreign objects.

Lidocaine-treated animals, like cocaine-treated animals (17–19, 22, 25), began to develop seizures in response to what was previously a subconvulsant dose (12). Following an average of 16 injections unassociated with convulsions, the animals developed generalized clonic seizures and then seized with increasing frequency and duration after subsequent lidocaine injections. Thus the progressive development of pathological eating behaviors as well as seizures with lidocaine suggest that effects other than those related to the stimulant effects of cocaine or amphetamine might be sufficient to produce some aspects of the reverse tolerance phenomenon.

MECHANISMS FOR PROGRESSIVE EFFECTS

Preliminary data suggest that the increased effects of chronic drug administration over time are not related to alterations in brain, plasma, or cerebrospinal fluid (CSF) levels of the stimulants or local anesthetics. Not only are cocaine and lidocaine metabolized very rapidly (36), but Mule (44) demonstrated that chronic administration of cocaine for 21 days in rats does not produce an increase in peak levels or half-life of cocaine in brain or plasma compared with an acute injection. Our preliminary data (22), obtained in collaboration with Richard Hawks, also suggest that the blood or CSF levels of cocaine in a monkey treated for more than 2 months are similar to those after the first injection.

Segal and Mandell (27) reviewed the evidence on blood levels of amphetamine and concluded that they are not likely altered with chronic administration. However, according to Kuhn and Schanberg (45), a focal brainstem area may have increased amphetamine

uptake. Ranje and Ungerstedt (30) demonstrated that amphetamine could interfere with learned maze behavior following injections as much as 12 days apart, and Mago (26) reported increased effects of amphetamine after a 6-week interval. Thus alterations in blood levels are an unlikely explanation for the progressive effects.

Conditioning phenomena, as described by Tilson and Rech (46), do not appear to adequately account for the progressive effects. Animals treated with cocaine did not demonstrate the typical stimulant-induced syndrome when given saline (22, 25, 27), and the de novo appearance of a variety of behaviors, such as stereotypies, dyskinesias, and convulsions, makes it unlikely that conditioning alone could account for the findings.

KINDLING

We were struck with the similarity in quality and time course of the effects of cocaine and lidocaine and the phenomenon of electrical kindling. The kindling effect was initially demonstrated by Goddard and associates (13) and has been extensively studied in various species by Racine (14), Wada and Sato (15), Pinel and Van Oot (16), and other investigators. Repetitive intermittent electrical stimulation of subcortical structures, particularly the amygdala, is associated with increasing duration and spread of after-discharges and local seizures, resulting in an animal's consistently having major motor convulsions in response to what was previously a subthreshold electrical stimulation. Although cortical tissue can be kindled with difficulty (13, 47), subcortical sites are more sensitive to the kindling procedure. The amygdala and related limbic areas are most sensitive, followed by the caudate and the hippocampus (13, 48). Wada and Sato (15) traced the development of the spread of seizure discharge following repetitive amygdala stimulation and indicated that it moves to the neostriatal system and then to the mesencephalic reticular formation before finally causing bilateral neocortical and generalized convulsive activity.

It should be emphasized that repetitive but intermittent stimulation is critical for the development of kindling and that chronic, nonintermittent stimulation will actually retard the kindling phenomenon (13, 49, 50).

Once an animal is kindled, the reduction in seizure threshold may last for more than 6 months, suggesting that a relatively permanent synaptic reorganization has occurred (13, 14, 49, 51). Most noteworthy for our purposes is the finding that the kindling phenomenon is not dependent on the manifestation of generalized seizures. The threshold for localized after-discharges unaccompanied by motor phenomena is also lowered following repetitive electrical stimulation (14, 51, 52). Thus seizures may serve as a marker for the kindling process but are not themselves a prerequisite.

A final note particularly relevant for later clinical interpretations of the kindling data is the finding that a chronically kindled animal may eventually exhibit spontaneous seizures (16); i.e., the kindling process may so facilitate neuronal pathways and seizure mechanisms that they discharge autonomously.

Pharmacological Kindling

Cocaine and lidocaine both have potent effects on limbic system structures, causing localized spindles, after-discharges, and seizures before they affect the cortical EEG (40–43, 53). Amphetamine alone or in combination with disulfiram also produces prominent alterations in limbic system activity (54, 55). We postulate that the stimulants and local anesthetics exert their progressive effects on behavior partly by means of a pharmacological kindling mechanism. That is, spindle and seizure activity in limbic system structures may increase after repeated doses, may be associated with increasing behavioral effects, and may become fully manifest in convulsions like those which result from electrical kindling.

In support of this concept, our data indicate that the progressive development of lidocaine-induced seizures is similar to the development of seizures evoked with electrical kindling. Not only do seizures develop and occur with an increased frequency in response to what was previously a nonconvulsant dose, but the seizures following lidocaine administration are qualitatively similar to those described with electrical kindling (13–16): rats rear back on their haunches and demonstrate intermittent clonic convulsions of head, trunk, and forepaws (12) in a posture characteristic of limbic seizures (13). Thus the time course, quality, and physiological focus of the effects of cocaine and lidocaine are all suggestive of a pharmacological kindling mechanism within the limbic system. Recent studies of the kindling hypothesis by Stripling and Ellinwood (23) and Ellinwood and associates (56, 57) indicated that repetitive cocaine administration produces progressive alterations in amplitude and synchronization of limbic spindles in the rat (23) and cat (57).

Pinel and Van Oot (16) emphasized the generality of the phenomenon of the progressive development of seizures after repetitive stimulation of the central nervous system. Table 2 presents a summary of studies of pharmacological, electrical, and audiogenic agents that have been associated with increased susceptibility to seizures. That the brain in some circumstances has the potential to increase facilitation or reactivity to repetitive, intermittent stimulation is supported by the variety of treatments capable of eliciting this effect.

The generality of a kindling-like phenomenon is also highlighted by the fact that repetitive administration of one treatment modality may sensitize the organism to another (16). For example, an electrically kindled animal is more susceptible to the effects of pentylenetetrazol (Metrazol) or the alcohol withdrawal syndrome; previous pentylenetetrazol and ECT treatments also exacerbate the alcohol withdrawal syn-

TABLE 2
Selected Studies of Agents Associated with Kindling-Like Increases in Susceptibility to Seizures

Study	Agent	Frequency of Administration	Animal Tested
Tatum and Seevers (17)	Cocaine	Once daily	Monkey
Downs and Eddy (18); Post (22)	Cocaine	Once daily	Rat
Post and Kopanda (11); Post and associates (25)	Cocaine	Twice daily	Monkey

Post and associates (12)	Lidocaine	Once daily	Rat

*Administered intracerebrally.

drome (16). In contrast to the generality of agents that are capable of progressively eliciting seizures, a specific and critical variable for the occurrence of progressive effects may be the frequency of their administration. Goddard and associates (13) found that there was an optimal interval (i.e., 24 hours) between stimulations for electrical kindling. Likewise, when many of the treatments listed in table 2 were given at intervals much more frequent than once a day they were not associated with increasing effects on seizures (16).

Kindling of seizures has been produced by direct intracerebral techniques, suggesting that cholinergic and dopaminergic pathways can be involved. For example, repeated, direct instillation of a previously nonconvulsive dose of carbachol (48), a drug that stimulates cholinergic receptors, produced seizures in rats. The amygdala was most sensitive to the drug, followed by the caudate and the hippocampus, which is the precise rank order of sensitivity of these anatomical areas to electrical kindling. Stevens and Livermore (63) reported electrical kindling of dopaminergic neurons in the area dorsal to the interpeduncular nucleus (A_{10}). These neurons, which project to the mesolimbic system, have been suggested as one locus of abnormal function in the schizophrenic syndromes (64, 65) as well as a site of action of the neuroleptics (66, 67).

Amine mechanisms, particularly alterations in receptor site sensitivity, are also implicated in some aspects of the reverse tolerance or kindling-like effects noted. Modigh (62) reported that repetitive ECT sensitizes mice to the activating effects of apomorphine and clonidine with reserpine pretreatment. Klawans and Margolin (28) demonstrated that chronic administration of amphetamine potentiates apomorphine-induced stereotypic behavior. Since apomorphine is a relatively specific dopamine receptor stimulator, these data suggest that alterations in dopamine receptor function, an "innervation supersensitivity" (28), may be involved in the increased effects of the stimulants on behavior over time. Rebec and Groves (68) confirmed these effects on the single neuron level, reporting increased suppression of neurons in the striatum and reticular formation with apomorphine following chronic, daily amphetamine pretreatment.

Increased receptor site sensitivity (28) on a depletion (69), denervation (70), or other (71) basis, although a possible biochemical mechanism for progressive behavioral and convulsive effects, would not be incompatible with a neurophysiological or kindling-like mechanism. Modification of receptor sites might mediate the synaptic facilitation (13) that appears integral to the kindling process. Moreover, Garcia and Mora (72) reported that repeated stimulation of the hippocampus produces histological changes consistent with an increase in RNA in synaptically related neurons.

Kindling Mechanisms and Behavior

We suggest that the amine potentiation produced by cocaine and amphetamine confers a unique behavioral syndrome on an underlying kindling-like or sensitization mechanism in the limbic system. Cocaine and amphetamine are thought to be potent stimulants largely because of their effects on catecholamines, which may be involved in effects on arousal, activity, stereotypy, insomnia, anorexia, and dependence (39, 67, 73–75). The amine effects in combination with a kindling-like mechanism may therefore help explain why the acute effects of the stimulants on mood progress to effects productive of a psychotic process. Acute cocaine administration is associated with prominent euphoria and dysphoria in man and hyperactivity and stereotypy in animals. However, more chronic administration of cocaine may be associated with paranoid psychosis in man and catatonic-like behavior and bizarre visual tracking and staring in animals (1, 21, 25). As in the electrical kindling paradigm, repetitive stimulant administration may also be associated with progressive increases in duration and spread of discharges associated with increasingly pathological behavior (23, 53, 57, 68). Accordingly, this model psychosis potentially implicates catecholamines, a limbic system focus, and a kindling-like or progressive mechanism.

Although lidocaine also has a limbic system focus for seizure activity (41–43) and produces progressive effects on behavior (12), its lack of effect on amine systems may explain why the behavioral changes produced with chronic lidocaine administration are qualitatively different from those produced by cocaine. The behavior seen during chronic cocaine or amphetamine administration in man and animals resembles that of the paranoid-catatonic spectrum, but the lidocaine-induced coprophagia and omniphagia (12) are markedly different.

Arieti (76) discussed the bizarre eating patterns in chronic "terminal stage" schizophrenic patients, who progress from a state in which they grab food at the sight of it to the habit of placing anything in their mouths, paying no attention to edibility. They may eat a variety of foreign objects, including "crumbs, cockroaches, stones, rags, paper, wood, clothes, pencils, leaves," and feces. Surgery has been required to remove intestinal obstructions, and a profusion of objects, including "spoons, stones, pieces of scrap iron, wood," have been found in the stomachs of patients on autopsy. It is noteworthy, in relationship to the chronic time course of kindling-like phenomena, that Arieti stated that this stage of schizophrenia occurs with chronicity, usually 7 to 40 years after the onset of the illness.

The almost automatic placing of objects in the mouth is reminiscent of the Kluver-Bucy syndrome produced by bitemporal hippocampalectomies in monkeys and man (77, 78); the tendency to put objects in the mouth in this syndrome is accompanied by an excessive reaction to every visual stimulus, visual agnosia, hypersexuality, and decreased aggression. Arieti (76) suggested that the behavior of some chronic schizophrenic patients, normal infants, and patients with bilateral temporal-limbic lesions may be related to a common primitive level of neuronal organization that is ordinarily inhibited or regulated by higher centers. The lidocaine-induced progressive development of omniphagia and seizures may represent a pharmacological means of producing this behavior by disrupting limbic-temporal areas rather than producing major effects on aminergic systems. When amine effects are added, as during chronic cocaine administration, the behavioral effects are qualitatively different, including anorexia and prominent alterations in activity, posture, muscle tone, and attention.

Psychological Kindling

What are some of the clinical implications of such a pharmacological kindling model for psychosis? MacLean (79) emphasized the importance of the limbic system in his description of the triune brain, suggesting that it is a critical intermediary between the phylogenetically older reptilian brain necessary for basic instinctual mechanisms and the newer neocortical overlay so prominently developed in the primate. Repetitive stimulation in a kindling-like fashion could produce a functional lesion or functional disconnection of the higher centers from the lower centers. Papez (80), Gellhorn (81), Heath (82), MacLean (79), Stevens and associates (64, 65), Gloor (83), Torrey and Peterson (84), and others have postulated that disruption of the critical limbic areas involved in emotion and cognition could be related to the onset or maintenance of pathological affective and schizophreniform states. What is new in our formulation is the suggestion of a mechanism that might mediate such disruption of limbic function, its progressive nature, and its possible interrelationship with known neurotransmitters.

One might speculate that the limbic system could also be progressively altered by spontaneous or endogenous activation of a kindling-like mechanism in man. In particular, it is possible that repetitive, stress-induced alterations in limbic system activity could produce progressive effects on behavior over time using mechanisms similar to those activated by cocaine or amphetamine. It is of interest that the effects of various experimental stresses on biogenic amines in animals and man can be similar to those produced by the psychomotor stimulants (85).

A rare insight into the possible relationship of limbic mechanisms and stress in man was provided by a study of Lesse and associates (86) that demonstrated that prominent limbic spindling could be associated with the mere recollection of previously stressful experiences. The idea of increased reactivity of the limbic system on the basis of previous experimental or psychological stimulation is consistent not only with electrical and pharmacological data but also with the known involvement of limbic mechanisms (particularly the hippocampus) in memory and learning processes (87, 88). The limbic system may be capable of memory-like or facilitatory processes for more complex, emotional cognitive behavioral patterns as well as seizures.

The Relationship of Kindling to Seizures

Although we are using a seizure model of kindling to explicate possible limbic and cortical mechanisms mediating some progressive behavioral effects of cocaine, seizures per se are not a prerequisite of the kindling model. High doses of cocaine and lidocaine were purposely used in several of the studies cited so that marked behavioral effects could be produced and seizures could then be used as precise end points for assessing increased response to repetitive administration. Studies using much lower (subconvulsant) doses of stimulants have also elicited profound effects in man (89) and increasing effects on the behavior of animals (22, 27, 28). Thus we are not suggesting that actual seizures, even in subcortical sites inaccessible to normal EEG techniques, are a necessary concomitant of psychopathological behavior. Abnormally facilitated pathways may have disruptive effects on behavior in the absence of seizures.

This idea is consistent with the kindling studies that demonstrated a decreased threshold to repetitive elec-

trical stimulation of the limbic system even in the absence of convulsions (13, 51, 52). Dissociation of the behavioral and convulsive effects of local anesthetics may also be achieved with diazepam, which blocks lidocaine convulsions but does not block omniphagia (according to our unpublished observations). Similarly, diazepam blocks kindled seizures (47, 90) but not the increased sensitivity to a given stimulus, as manifested by a decreasing threshold for after-discharge (90). Because temporal lobe, limbic, and local anesthetic seizures may be closely associated with behavioral effects and may share common pharmacological mechanisms that are opposite those for most classical (cortical) models (40, 53, 89–91), behavioral effects rather than classical seizures would be the expected outcome of a kindling-like mechanism in man.

CLINICAL AND THEORETICAL IMPLICATIONS

A kindling mechanism may provide a critical conceptual link between the occurrence of chronic temporal lobe epilepsy and the later onset of psychosis. With repeated temporal lobe seizures, a kindling process could occur in which the temporal lobe activity progressively expanded to include other neural substrates, possibly those deeper in the limbic system.[1] The incidence of psychotic behavior in temporal lobe epilepsy increases with either the duration of the seizure disorder (93) or the interval between seizures (94). These clinical measurements match both the repetitive and intermittent nature of the electrical stimulation required to produce kindling.

As mentioned above, the kindling model might provide an explanation for the sensitivity of a former amphetamine addict to the recurrence of delusions even after months of abstinence (31). It is noteworthy that Bell (95) reported that the only 2 patients of 16 given high-dose, intravenous amphetamine who did not develop a paranoid psychosis were later found not to have had a history of long-term abuse. Previous repetitive stimulant administration may have altered the patients' susceptibility to amphetamine psychosis.

The kindling model for the progressive development of psychopathological behavior could also help conceptualize mechanisms by which environmental events might sensitize patients to acute exacerbations of illness. Chapman (96) emphasized the paroxysmal onset of some psychotic behaviors in acute schizophrenic patients. Episodic emergence of psychopathology could be interpreted in terms of sudden reactivation of previously facilitated pathways triggered by adequately stressful stimuli. Similarly, activation of predominantly excitatory or inhibitory limbic pathways (78, 83, 97) might be considered in the acute onset of affective psychoses (98). Although some patients with affective illness appear to have identifiable precipitants to their episodes, others have episodes with such precise regularity (e.g., every 48 hours) that specific psychological determinants for each mood can virtually be ruled out. Like seizures that can begin to erupt spontaneously with very chronic electrical kindling (16), "spontaneous" affective episodes might also emerge following sufficient repetition and stress. As lithium has been shown to increase thresholds for after-discharges in the limbic system (99), its unexplained effects in both mania and depression might be explored in terms of a common effect on a kindling-like mechanism.

Finally, the kindling model fits the criterion for a "functional" alteration, which is required for models of affective and schizophreniform psychoses since no neuropathology has been demonstrated in these illnesses. Moreover, abnormal discharge of neural pathways, an "active lesion," may be capable of producing more profound deficits in behavior than are destructive lesions or ablations and may be less readily compensated for (100). One of the advantages of the cocaine-kindling model would be that it focuses on functional synaptic changes and plasticity in the central nervous system without requiring a specific anatomical or pharmacological lesion.

Thus we could postulate abnormal facilitatory or inhibitory pathways that involve a variety of neuroanatomical structures and transmitters corresponding to a variety of different types of psychopathological presentations in the acute psychoses. The neurophysiological-biochemical model does not require a given lesion to explain multiple behavioral syndromes; it invokes a pathological process involving activated pathways that could act as a series of lesions. The model highlights the capacity of the central nervous system to react to a variety of stimuli in a progressively pathological manner, potentially making use of substrates ordinarily involved in normal learning and memory. Exploration of a kindling-like sensitization process in relation to behavior may help close the methodological and conceptual gaps between neurobiological and psychological approaches in psychiatry.

[1]McIntyre and Goddard (92) demonstrated that repetitive cortical stimulation is capable of producing kindling-like effects in limbic structures, as well as vice versa.

The "Intoxication State of Consciousness": A Model for Alcohol and Drug Abuse

BY MARC GALANTER, M.D.

The author describes a model of intoxicant use based on altered states of consciousness and reviews his own and others' research on marijuana to illustrate the utility of this model, which is derived from both introspective reports and observed data. The relationship of social behavior and cognitive functioning to the "intoxication state of consciousness" is discussed. This state of consciousness may have an adaptive value in engendering and stabilizing social cohesion. Possible treatment implications include cognitive labeling of cues that precipitate episodes of abuse, training for moderated drug use while patients are intoxicated, and providing abusers with altered consciousness through other means, such as meditation.

DIFFERENT PSYCHIATRIC traditions have generated clinically useful models of alcohol- and drug-seeking behavior. This paper, based on studies conducted at the National Institute of Mental Health on the social intoxicant marijuana (1–6), will integrate our data with those of other investigators in an attempt to support the utility of a model of intoxicant use related to altered states of consciousness. I will also discuss the relevance of the concept of an intoxication state of consciousness in dealing with drugs of abuse.

MODELS OF DRUG ABUSE

Psychoanalytic thinking has engendered a model of alcohol abuse predicated on the development of oral fixations and unmet dependency needs generated by oral frustrations in childhood (7). The necessity to deal constructively with these needs in order to sustain treatment has been acknowledged (8).

Interpersonal relationships are also thought to play a role in precipitating a pattern of intoxicant abuse. For example, Berne (9) applied his model of transactional analysis to characterize the "alcoholic life game," and other games typical in alcohol abuse have been described (10). Alcohol use has also been said to play a role in maintaining the homeostasis of family systems (11) and in stabilizing nonfamilial interpersonal networks (12).

Another approach, drawn from the *medical model*, is to designate intoxicant abuse as a disease. Jellinek elaborated on this model in *The Disease Concept of Alcoholism* (13). He outlined the stages in the course of the disease along with their respective symptoms in a way that parallels the evolution of other chronic illnesses. Also related to the medical model is Dole and Nyswander's hypothesis that since heroin addiction is a disease with physiological substrates, some addicts may become permanently dependent on opiate administration (14).

Another model is Wikler's application of a *pharmacological conditioning paradigm* to opiate addiction (15, 16). One treatment approach suggested by this model is based on extinction of the conditioned drug-craving response by administration of the drug under circumstances in which reinforcement is not possible, such as after administration of a narcotic antagonist (17). Extinction of a craving response in alcoholics has been attempted by administering apomorphine to precipitate vomiting and thus serve as a negative reinforcer as one engages in drinking behavior in a treatment setting (18).

ALTERED STATES OF CONSCIOUSNESS

Contemporary psychiatric research is generally conducted on the level of behavioral phenomenology and/or neurophysiology. Around the turn of the century, however, it was felt that psychological investigation should be introspective and that its subject matter should be the immediate conscious experience of the subject within himself (19). Introspection, the controlled observation of the contents of one's own consciousness, was deemed the principal tool for the scientific study of psychology. William James reasoned that "the distribution of consciousness shows it to be exactly such as we might expect in an organ added for the sake of steering a nervous system grown too complex to regulate itself" (20, p. 144).

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Galanter is Career Teacher in Alcoholism and Drug Abuse and Assistant Professor, Department of Psychiatry, Albert Einstein College of Medicine, Bronx, N.Y. 10461.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant DA-00197 from the National Institute on Drug Abuse.

This approach was useful in understanding alterations of consciousness seen in certain religious experiences, as reflected in James's *The Varieties of Religious Experience* (21), and highlights some of the difficulty in applying contemporary psychiatric nomenclature in dealing with the recent revival of fundamentalist religious sects (22).

Rapaport (23) described variables that may distinguish states of consciousness within the psychoanalytic frame of reference as follows: 1) the degree of reflective awareness, i.e., the capacity to be aware of thought content and become aware of this awareness, 2) the ability to exert effort or will, and 3) the formal characteristics of thought, such as primary or secondary process thinking. Ludwig defined an altered state of consciousness (ASC) as

> any mental state(s), induced by various physiological, psychological or pharmacological maneuvers or agents, which can be recognized subjectively by the individual himself (or by the objective observer of the individual) as representing a sufficient deviation in subjective experience or psychological functioning from certain general norms for that individual during alert, waking consciousness. (24, p. 235)

Tart (25, 26) further elaborated on what is in effect a typology of discrete states of consciousness. These states are defined on the basis of their "hardware" (biological and physiological givens) and "software" programs (engendered by learning and acculturation). A multidimensional space, with each dimension representing a hardware or software variable, may be used to map out various discrete states of consciousness.

As one defines such boundaries for particular states of consciousness, similarities may be noted among the various states. For example, in our marijuana studies we found increased alpha power in the EEG during intoxication (4, 5). Certain meditative states may be similarly characterized (27, 28). Indeed, intoxication with psychotomimetic drugs is similar to various meditative states along a variety of experiential dimensions (29).

Work by Sperry and associates (30), who studied commissurotomy patients, may suggest an approach to understanding the stabilization of ASCs. Galin (31) related the cerebral dissociation phenomena that Sperry and associates described to Freud's topographic model of the mind, wherein repressed mental contents function in a separate realm inaccessible to conscious recall. They liken certain aspects of right cerebral function to the cognition referred to as primary process, being predicated on nonverbal representation of imagery, nonlinear logic, and lack of involvement in the perception of time and sequence. One might similarly speculate that other neurophysiological or functional neuroanatomical features of the brain may serve as a basis for the differentiation of ASCs under certain circumstances.

A systems approach is useful in defining a state of consciousness as an open system influenced by a variety of factors that impinge on it and alter its nature and stability. Our findings (1, 2, 4, 6) and those of other investigators (32, 33) indicate that the context is of major importance in determining the nature of the marijuana-induced subjective state. For example, very few if any medical reports from nineteenth century Europe indicated that patients for whom marijuana was prescribed were "stoned" or that their significant interpersonal relations were materially affected (34).

Just as one drug may produce somewhat different states depending on context, the same state-dependent parameters may be engendered by different determinants. We found, for example, that average evoked response patterns in marijuana-intoxicated subjects bore certain resemblances to those of schizophrenics when the same protocol was experimentally applied to both groups (5). This appears to reflect an ability of marijuana-intoxicated subjects to "tune out" the outside world and establish a temporary autism. This autism was also reflected in our findings on intoxication in a social context (6): the principal cognitive factor differentiating the active drug state from the no-drug and placebo states was a sense of detachment from the ongoing interactions of the social group.

CHANGES IN EXTERNAL PERCEPTION

Relating neurophysiological findings to metapsychological constructs may be useful in integrating experimental data. Shevrin (35) studied average evoked responses using subliminal cueing and illustrated a relationship between this physiological indicator and unconscious thought processes involving attention and perception. As I have mentioned, our marijuana-intoxicated subjects showed a decrease in the magnitude of evoked responses to both frequent and infrequent stimuli. It seemed plausible to presume that during intoxication our subjects paid less attention to auditory stimuli that they were told to ignore than they did after smoking no drug or placebo marijuana. Apparently, after smoking marijuana these subjects were able to turn down the "volume" of environmental input.

A related phenomenon is observed in marijuana-induced changes in the contingent negative variation (CNV). The CNV is a slow cortical potential that can be recorded immediately before a stimulus that is anticipated by the subject (36). Kopell and associates (37) found that THC enhances the amplitude of the CNV and surmised that this illustrates an increase in the complex function of attention-arousal that is represented by the CNV. This change in attention may be due to the reduction in distracting external stimuli that has been reported by users of the drug (38).

Another example of enhanced function is found in the work of Hill and associates (39), who studied the critical flicker fusion during marijuana intoxication and found an increased sensitivity in distinguishing intermittent light flashes, as well as an increased sensitivity to painful and nonpainful stimulation. These findings

illustrate some of the enhancement of certain functional capacities by marijuana, which may be construed as beneficial by the smoker. Various subjective reports have indeed indicated that marijuana users find their perceptual awareness heightened when they are intoxicated (38, 40, 41).

THE SUBJECTIVE EXPERIENCE OF INTOXICATION

Because of their predictive value in studying physical phenomena, inductive, reductionistic scientific techniques have popularized the assumption that reality is reducible to objectively defined physical components. Paradoxically, if one is studying subjectively experienced states of consciousness, subjective experience must be a primary source of data. Such data are often regarded as obstructive or irrelevant to accurate quantitative measurement.

We found, however, certain remarkable consistencies in the measurement of a smoker's subjective experience during marijuana intoxication (1). It appeared that this internal state was as reliable an indicator as physiological measures such as pulse change and blood concentration of labeled cannabinol. For example, subjects' totals for individual symptoms on a symptom checklist administered during intoxication correlated remarkably highly with their scaled global rating for the subjective variable of how "high" they were ($r=.94$, $p<.01$, Pearson product-moment correlation). In addition, there was a high rank-order correlation between symptoms in the active drug and placebo states ($r=.544$, $p<.01$). Apparently, the subjective experience of the marijuana state can be summoned up with remarkable accuracy by the cue of smoking placebo cigarettes.

What was puzzling was our finding that the only subjective experiences reported consistently after smoking marijuana in an experimental sensitivity group setting were somesthetic (e.g., dry throat and mouth, hunger, dreaminess, slower movement, and head feeling heavy) rather than affective (6). Apparently, individual subjects responded relatively consistently to marijuana, as indicated by self-report, but the subject-specific affective responses "washed out" when the data were analyzed for all subjects as a group. This is compatible with the assumption that ASCs may best be studied by having the individual characterize his own introspectively described experience rather than attempting to generalize across subjects. This approach would hark back to the introspectionist school of psychology.

STATE-DEPENDENCY

State-dependent learning was first observed in experimental animals exposed to learning paradigms after the administration of curariform drugs (42). These animals were better able to reproduce the learned material when the drug was readministered than when they were in the drug-free state. In recent years this phenomenon has been reproduced in human subjects intoxicated with alcohol (43–45). It has also been demonstrated with marijuana (46–49), both for recall of specific items and for reconstruction of rules that the subject himself had generated to learn experimental material.

It may be that certain aspects of state dependency contribute to the inability of drug abusers to carry over volitional capacities from sobriety to the drug state. The differential organization of cognitive traits during drug intoxication may result in ASCs in which basic learned and unlearned traits related to personality and adaptation are evident only in the particular ASC itself.

ETHOLOGY

One approach to understanding the role of an intoxication state of consciousness is derived from ethology, the comparative study of animal behavior. In the past 25 years ethologists such as Lorenz (50) and Tinbergen (51) have made major contributions to behavioral biology. Bowlby (52), discussing the relevance of ethology to the study of complex human behaviors, pointed to nest building and courtship behavior among birds to illustrate the complexity of behaviors whose substrates may be genetically transmitted. He also described the work of Dennis (53) and Spitz and Wolf (54) on the smile response in infants, a social behavior that may be physiologically based and organized in such a way that it may be evoked by appropriate "social" stimuli at around 6 weeks of age.

Ethologists describe similar behaviors present in different species as analogous when they have been developed by the different species in order to adapt to similar external circumstances (50). Animal behaviors similar to those of humans have been studied in order to shed light on human behavior (55–57). The roles played by ASCs as part of ritualized group phenomena have analogous counterparts in almost all cultures. Such states may be precipitated by social intoxicants or by interpersonal cues. In the context of an ethological approach, one might presume that ASCs have now or have had in the past an adaptive value, thus assuring their ubiquitous presence (58).

Displacement activity may occur when discharge of a surplus of instinctually derived motivation through normal channels is prevented. This most commonly happens when two antagonistic drives are operating or when the expression of an instinctual need is blocked by external factors. The displacement activity then becomes a strongly motivated behavior typical of another drive, with no adaptive value in the context where it appears. Weigert (59) likened this phenomenon to the development of neurotic symptoms. Under certain circumstances, one might consider the expenditure of excessive amounts of time in a drug-induced ASC as a

displacement activity generated by obstruction of the discharge of instinctual drives. An illustration would be the use of intoxicants for anxiety that results from conflicting drives.

It might be added that the ethological approach to explaining certain behaviors need not contradict the application of learning theory. For example, a responsivity necessary to initiate and terminate biologically based behaviors may be acquired by conditioning (52). This fact can be related to the constructs developed by Wikler (16) and Ludwig and associates (60) regarding the conditioning of interoceptive and exteroceptive cues to initiate the addictive use of opiates or alcohol or to precipitate relapse.

INTOXICANTS AND SOCIAL BEHAVIOR

In our study on marijuana and social behavior (6), subjects assessed their experience in sensitivity group meetings conducted after they had smoked either active marijuana, placebo, or no drug. Before the meetings these subjects had characterized their previous experiences of the social use of marijuana as happier, friendlier, calmer, and less defensive than their experiences in social situations while not "high." Meetings that were held in the active drug state were assessed by subjects as more relaxed and happier. This illustrates one aspect of the role that intoxicants may play in facilitating more stable and cohesive group interactions. Transcultural studies (61) support the adaptive value of ASCs in terms of the development of social cohesion and dealing with (or "curing," as the case may be) behavioral deviancy.

The capacity of intoxicants to stabilize a social system is illustrated by phenomena such as the diminution of aggressive and pathologically regressive behavior among alcoholics experimentally given the opportunity to share in the function of alcohol acquisition (62), the drinking gang in naturalistic settings (12), and the alteration by alcohol of roles within the family system serving to maintain homeostasis (11). Similarly, the widespread use of marijuana among farm laborers in Jamaica has been suggested to serve the adaptive function of increasing social cohesion in the group labor situation (63).

RELEVANCE OF THE MODEL

If there is a biologically based adaptive proclivity for altered consciousness, such as that produced by social intoxicants, we may be able to observe analogous behavior in other species. Crowley and associates (64) pointed out that other primates may be appropriate subjects for the study of pharmacological effects of drugs of abuse on social behavior and reported on initial studies in this area.

The adaptive value of social intoxicants may be underestimated by physicians in an attempt to label the alcohol abuser as victim of a disease. The altered state the abuser achieves may be valuable in assisting him to sustain an equilibrium within his particular social context. It thus becomes of central importance to ascertain what adaptive traits the intoxication state provides a given patient and to then assist him to develop the capacity to achieve such ends without recourse to the intoxicants (65).

The discrete quality of the intoxicated state, particularly in relation to state-dependent learning, may enable us to better understand how cognitive and volitional capacities that exist during sobriety may be unavailable during intoxication. Many of our endeavors in combating intoxicant abuse are dependent on the capacity of the abuser to carry over learning from sobriety to intoxication. Perhaps some of the training should be conducted while the subject is intoxicated. Social drinkers have been trained to gauge their own blood alcohol concentrations with feedback from breath analyzers (66, 67). Similar approaches are now being used with alcoholic patients to provide them with a cognitive framework to apply during the intoxication state (68).

In order for the intoxicated subject to develop a more effective capacity to sustain his volition in the altered state, cognitive labeling (17) of the interoceptive or exteroceptive cues that precipitate an episode of abuse should be maximized. This might enable the abuser to prevent loss of control after he passes into the intoxicated state. The potential viability of such an approach is suggested by the experimental use of verbal cues to reverse state-dependent learning deficits during marijuana intoxication (69).

If it is the altered state of consciousness that attracts the abuser, then the option of achieving such altered states by other means should be considered as potential treatment. One such approach is the use of meditative states. Many practitioners of meditation were involved in the wave of adolescent drug use in the late sixties. Benson (70, 71) reported preliminary work indicating decreased intake of alcohol and other drugs of abuse among initiates to Transcendental Meditation.

Prompt Publication Policy

The *Journal* would like to remind authors who are particularly interested in early publication (whether to establish priority of an idea, reveal innovative results of new research, or for other pressing reasons) of its prompt publication policy. Under this policy, short (maximum of six double-spaced pages) manuscripts will be considered for publication in the Brief Communications section of the first available issue. These manuscripts must still undergo expert scrutiny before being accepted, and two months must be allowed for the printing process. However, the time required for publication of these short articles can be lessened considerably.

Authors who would like to have their manuscripts considered under this policy should indicate this desire, as well as the reason for it, when they submit their manuscripts.

The Future of Alcohology: Craft or Science?

BY MELVYN KALB, PH.D., AND MORTON S. PROPPER, M.S.W.

The authors discuss the problems that have resulted from the influx of professionals into the field of alcoholism, which has historically been dominated by paraprofessional workers. The interaction of the professional alcohologist, who operates from a scientific model, with the paraprofessional worker, whose model of treatment has followed craft lines, has created unique problems and tensions. A synergism has been created which has been detrimental rather than complementary. The authors suggest that the future of the alcoholism field will have to be established along craft (paraprofessional) or scientific (professional) lines because the two models cannot profitably co-exist.

A NEW TYPE of manpower, the professional alcohologist, has emerged on the alcoholism treatment scene as an outgrowth of the recent rich infusion of federal attention and funding through the establishment of the National Institute of Alcohol Abuse and Alcoholism (NIAAA).

While manifestly operating in harmony with the veteran nonprofessional, this influx of new professionals in the alcohol field has created unique problems and tensions. Unfortunately, the conflicts and frictions between the professional and paraprofessional have not been allowed to surface. Rather than attempting to resolve the problem, the approach has been to deny its existence.

The purpose of this paper is to illustrate and review the evidence of these conflicts, to trace their history and consequences, and to provide the reader with some explanatory hypotheses. Our intent is not only to provide a perspective on the problem but to stimulate dialogue in the belief that only with candid self-examination is there hope that the clinical alcoholism enterprise can meet the high expectations of the "new era" in alcoholism study and treatment.

When this work was done, Dr. Kalb was Coordinator of Research and Education, Santa Clara County Alcoholism Program, San Jose, Calif., where Mr. Propper is Clinical Social Worker. Dr. Kalb is now Clinical Psychologist, Department of Psychiatry, Kaiser-Permanente Medical Group, 900 Kiely Blvd., Santa Clara, Calif. 95051.

The opinions expressed herein are those of the authors and do not necessarily reflect the views of the Santa Clara County Alcoholism Program, the Santa Clara County Public Health Department, or the Kaiser-Permanente Medical Group.

The authors wish to thank Drs. Robin Room and Marc Schuckit and Mr. Ron Roizen for their invaluable suggestions.

"CRAFT" VERSUS "SCIENTIFIC" MODELS OF ORGANIZATION

The context in which the conflicts between the professional and nonprofessional in the alcoholism field can best be understood is the distinction between craft and scientific models of organization. A craft as opposed to a scientific organization can be defined by differences in acquisition of knowledge, implementation of knowledge, and the nature of loyalty among its members.

A craftsman gains his qualifying skill (knowledge) primarily through direct observation and experience under the tutelage of a master craftsman. The knowledge he acquires is a product of the experiences of his teacher. The test of the craftsman's learning is his demonstrated ability to consistently replicate the performance of his teacher. Acceptable deviations are limited largely to elaborations of style; critical analyses of the overall traditions of the craft are actively discouraged. In fact, mutual agreement is the basis on which loyalty is established among the membership of a craftlike organization.

By contrast, the scientist-professional learns his skill not only experientially in a journeyman-apprentice relationship but also in a context relying on the cognitive teachings of many others. The scientist-professional in training is exposed to a broad variety of competing viewpoints and is encouraged to exercise autonomy in establishing his own conceptualization of the issues (1). Although there are craftlike aspects within the scientist-professional model (2), the demonstrated ability to engage in unique, independent thinking and to critically evaluate the work of one's teachers and peers is the sine qua non of the scientist-professional model.

It is this critical analysis and quest for new solutions using a body of mutually held methods (empiricism, rationality, and freedom of investigation) that establishes a bond of loyalty among scientists. The members of a scientific profession are not united by presenting a unified front against their critics but rather by a methodology that provides the tools for resolving disagreement.[1]

Paraprofessional preparation for service in the field

[1]Alfred North Whitehead (3) made the following distinction between a craft and a profession: "A craft is based upon customary activities and modified by the trial and error of individual practice. A profession [consists of activities] which are subject to theoretical analysis and are modified by theoretical conclusions derived from that analysis" (pp. 73–74).

of alcoholism has clearly followed the craft model outlined above. The indoctrination of new members in the philosophy and principles ("12 steps") of Alcoholics Anonymous by teachers who are recovered alcoholics (and who followed the same course of learning and rehabilitation), the prescription to think and act as their teachers do, and the goal of one day being like their teachers and teaching others the same philosophy characterize the apprenticeship of the paraprofessional.[2] The strong devotion of most paraprofessionals in the field of alcoholism to traditional concepts, their general resistance to serious consideration of alternative views and studies on the nature, course, and treatment of alcoholism, and their steadfast refusal to question their own premises in the light of conflicting evidence all serve to create an intense loyalty and unity.

As long as the alcoholism treatment enterprise was composed of an overwhelming preponderance of paraprofessionals, this craftlike organizational structure was appropriate and beneficial. It was only when professionals with their own scientific organizational model came on the scene that the perpetuation of the craft model became questionable.

It is our thesis that the future of alcohology will have to be established along either craft lines, exemplified by the paraprofessional alcoholism counselor, or scientific lines, embodied by the professional scientist. Because the defining properties and operational principles required for membership in a craft are different from those of a science, a détente would be difficult to achieve. The point is *not* that either approach is superior, but that the marriage of the two prevents growth and progress. The synergism that is created acts in a negative rather than a complementary way.

HISTORY OF THE PROBLEM

The clinical treatment of alcoholism has been governed largely by lay groups of recovered alcoholics. This group of dedicated individuals, acting in response to the benign neglect and abdication of the helping professions, banded together to fill the vacuum in the treatment of alcoholics. The predominant group has been the fellowship of Alcoholics Anonymous. Prior to the implementation of NIAAA in 1971, professionals in alcoholism treatment represented a scant fraction of the manpower in the field (5, 6).

While the number of professionals in the alcoholism field has increased dramatically, professionals are still a small percentage of the total manpower pool (5). This disproportionate distribution of professionals and paraprofessionals has continued to place the power, both political and clinical, in the hands of the nonprofessional.[3]

This distribution of power between professionals and paraprofessionals in the treatment of alcoholism is in marked contrast to that in the mental health field. Professionals have entered the field of alcoholism treatment after more than two decades of paraprofessional dominance, while the trend in the mental health field in the last decade has been in the opposite direction—the recruitment of paraprofessionals to join the ranks of the professional (7, 8). Moreover, while the paraprofessional in the mental health field has functioned adjunctly to and under the supervision of the professional, the paraprofessional in the alcoholism field has been a teacher or colleague rather than a student.

By virtue of this power, lay groups in the alcoholism treatment field have been and continue to be the gatekeepers of clinical knowledge and clinic operating style. Thus, despite a growing research literature that has pointed to new directions in the conceptualization of etiologic and therapeutic models, empirically unvalidated clinical notions regarding the nature of alcoholism persist. These clinical notions have firmly established themselves as traditional and inviolate wisdoms. Their survival is ensured by the protection provided by their disciples in the form of intense loyalty to them. Examples of this loyalty and the sometimes fierce attacks visited on the "heretic" are numerous (9–13).

Jerome Ravetz, in a recent book on the philsophy of science and its social problems, discussed the general problems of the relationship between the growth of an empirically based scientific establishment and the attendant conflict with the preexisting body of beliefs and doctrine (which Ravetz labels "folk science").

> Value [of the folk science] is determined by the degree to which a problem situation is central to the experience of the audience; and adequacy by the success in offering reassurance and the promise of understanding. . . . The conflicts between academic science and strongly based folk sciences provide many insights into the social situation of science, and into some insoluble problems inherent in that situation. [One such problem] occurs when the results of a disciplined scientific inquiry contradict the beliefs of a folk science, usually a popular one which is also adopted by the established cultural organs of society. (2, pp. 388–389)

As is the case in all craft organizations, this loyalty to traditional concepts is the "glue" that binds the nonprofessionals in alcoholism treatment (14). Toch (15) pointed out that all self-help groups have by definition an inherent antiprofessional bias. Pattison noted that a self-help group also has

> a self-fulfilling prophecy of success, and the validation of its theories is ideological rather than scientific. However, these elements of a self-help group are the "social glue" that holds a self-help group together, promotes co-

[2]It is interesting that the book *Alcoholics Anonymous* (4) is commonly referred to as "the Bible." The implications of this nickname are obvious.

[3]It is obvious that if nonprofessionals suddenly stopped working with alcoholics, alcohol treatment programs would be brought to a halt. This would not be the case were the professionals to pursue a similar course.

> hesion and integration, validates hope and commitment and in short makes it work! (14, p.620)

One of the most serious (and costly) by-products of this ideology is the lack of integration of research findings into the mainstream of the clinical treatment of alcoholism. Research in the treatment of alcoholism and the actual clinic treatment of the alcoholic have been allowed to coexist, but rarely (if ever) to intersect.[4]

Research findings (especially those not in keeping with the "party line") seem to have been simply ignored by the paraprofessionals. They have died not because of contradictory research studies or polemic discussions, but simply by being disregarded. In fact, vigorous and open scientific debate rarely occurs within the alcohol treatment setting. What does occur is either personal invective directed against the speaker or writer who presents "heretical" findings (the *data* being ignored) or systematic attempts to smother debate, with the rationale that "We are all in the field to help the alcoholic so let's not argue."

Filstead and Rossi (16) have pointed out that a publication in the 1940s, "Alcohol, Science and Society" (17), dealt with issues and problems that predominated in the era of the forties and still persist in this decade. They asked why there had not been more progress.

Some answers to this question might be found by questioning directors of alcohol treatment centers as to the amount of change in the last 10 years in the functioning style of their clinic and/or the treatment offered to the alcoholic that originated not from political and community pressures but directly from published scientific findings. It might be more frightening and revealing to ask how different the psychotherapeutic clinic treatment of the alcoholic would be had there been *no* scientific research on the treatment of alcoholism published in the last 25 years. Ludwig, discussing the assets and liabilities of the mental health system's approach to the alcoholic, noted that

> there are not enough searching and probing questions or effort expended to accumulate more facts. . . . In fact the current service oriented professional mentality is such that research is not only discouraged in many treatment settings but also regarded somehow as suspicious and even immoral. (18, p.152)

An example of the blatant disregard of scientific findings in the alcoholism treatment field is the belief that one drink triggers an uncontrollable urge in an alcoholic to keep drinking. A recent article by Paredes and associates (19) reported that this hypothesis as it is commonly understood is not supported by empirical evidence. The authors underscored the results of their own research by citing similar findings in 20 previously published studies. Mendelson (20), the first chief of the National Center for the Prevention and Control of Alcoholism, reported that his own experimental work showed no evidence for such an automatic biochemical triggering effect. Despite the overwhelming weight of empirical evidence against this hypothesis and the absence of any substantiating scientific evidence, it continues to flourish in the ideology of alcoholism treatment and philosophy as if it had been confirmed time and time again.

The work of Cahalan (21) serves as a variation on the same theme. Cahalan found that many men with serious drinking problems are able to change their drinking habits and "mature out of" problem drinking without therapeutic intervention. He also found that the largest proportion of serious alcohol-related problems are in men in their early twenties, who have apparently high rates of maturing out (spontaneous remission) in their early thirties.

Cahalan's findings raise serious questions about the validity of the "progressive illness" concept of alcoholism as it is commonly understood. Pattison (22) pointed out almost 10 years ago that the well-known Jellinek chart illustrating the progressive and disastrous decline of physical and emotional health that accompanies alcoholism was based on a biased sample of Alcoholics Anonymous members who were physically and socially bankrupt. Ironically, in his original article, Jellinek (23) pointed out that many people remain "stuck" at a given level of alcoholism behavior. This point, generally unknown or ignored, is not reflected in the famous "progressive illness" chart.

It seems that scientific research in alcoholism occupies a unique position. Research is not used, as in other fields, as a springboard for developing and testing new hypotheses and abandoning old ones that are empirically disproved. Alcoholism treatment concepts in the overwhelming majority of clinic settings have developed and survive not with the aid of research but in spite of it. Clinical treatment is not the logical outgrowth of scientific discoveries but instead remains an encapsulated body of theories and shopworn slogans that are apparently immune to the outcome of scientific research.

The unencumbered flow between research and clinic treatment that Chafetz (24) has called for can occur only in an environment in which the practicing clinician is free from a personal investment in the perpetuation of a particular theory or construct. It is only in such an environment that clinicians can choose therapeutic concepts on the merits of scientific evidence. It is paradoxical that personal investment and the lack of openness to new findings and fresh conceptualizations are the hallmarks of the typical alcoholism treatment setting.

Ludwig, writing about the role of innovation and the use of research findings in the alcoholism treatment system, noted,

[4]This isolation of research from clinic realities has now been institutionalized into the annual NIAAA National Conference. Three separate "tracks" have been established—research, treatment, and prevention—all of which present papers and discussions concurrently. Interactions among individuals in these three areas are made impossible by this design.

> Despite the embarrassingly poor long-term results of most treatment and rehabilitation programs, enormous sums of money and staff time are being spent to perpetuate traditional approaches (and various mythologies) rather than being diverted to innovative demonstration projects. It is as though the underlying philosophy of these programs is based on the principle that if sufficient manpower can be deployed to employ ineffective procedures then this multiplication of ineptness will hit therapeutic paydirt. (18, p.152)

A clinical field that claims to employ scientific principles and theories in the service of helping the alcoholic while creating a climate in which research findings are ignored and disregarded aligns itself to anachronisms, sloganeering, and opinion rather than to science. Ullman and Krasner posed the question that might eventually be put to the alcoholism treatment system: "If a particular theory does not utilize data based on scientific procedures, it may well be asked whether it is a reasonable basis for the treatment of human beings" (25, p. 36).

COGNITIVE STYLES AND COMMITMENTS OF PROFESSIONALS AND PARAPROFESSIONALS

There is an obvious divergence of learned cognitive styles between professional and paraprofessional workers. Most professionals have been trained to use an analytical-objective-inductive cognitive style. Their long years of schooling have not only emphasized a respect for inductive empirical reasoning but also equipped them with the skills to interpret and critically evaluate empirical research data. The paraprofessional usually lacks this training and uses an intuitive-subjective-deductive cognitive style. Empirical data are often perceived as obscure and irrelevant, especially when they conflict with intuitive, experiential understanding.

This contrast in cognitive style is reflected in the early literature on alcoholism treatment. Much of the early research was conducted without the experimental controls vital to sound experimentation, and the literature consisted mostly of anecdotal reporting (26). The popular view of alcoholism was created largely by laymen (5) and fashioned out of their personal experience.

The intensely personal commitment the recovered-alcoholic paraprofessional may feel to the traditional model of alcoholism is quite understandable. The traditional model defines the alcoholic as the victim of a disease, entitling him to many social services for the disabled. It also saves the recovered alcoholic from the moralistic stigmata of "weak character" and "mental illness" (27). Thus, the recovered-alcoholic paraprofessional's self-esteem is often a very real part of his "stake" in sustaining the traditional views of alcoholism. The individual who, for example, has the deep conviction that his sobriety rests solely on his acceptance of the tenets of Alcoholics Anonymous or on some other traditional understanding of alcoholism is likely to feel deeply and personally threatened by any information that might call those understandings and interpretations into question.

For the professional, a challenge to traditional beliefs is often an academic issue for debate, but for the recovered alcoholic, it often becomes a threat to his sobriety, his stability, his job, and his very existence. It is quite understandable that a recovered alcoholic whose sobriety is founded on abstinence may, for example, be deeply disturbed by the idea that some alcoholics can recover and drink socially. Selzer (10) maintains,

> Perhaps another important reason for the almost reflex rejection [of normal drinking in recovered alcoholics] is that many people working in this field are alcoholics themselves and are compelled to remain abstinent. It may be especially difficult for the alcoholic who must remain dry to accept the idea that others can recover and drink socially. To hear of the "success" of others may be frustrating—and those workers prefer not to hear about it since it also upsets their treatment concepts. . . . Granted that experimentation will yield discouraging relapses in most instances, this is not sufficient excuse for prejudiced persons to vilify the truth. (p.133)

IMPLICATIONS OF THE INFLUX OF PROFESSIONALS

The professional is rather in the position of a newcomer or, in some cases, a tentatively welcome visitor in the "house" of alcoholism treatment. He may very well feel that he must, like a visitor, be on his best behavior and be sensitive to the house rules. His "gifts" and talents (clinical skills, inductive and analytic reasoning) are viewed with suspicion and/or contempt. He must tread carefully because, on a practical day-to-day level, he is the most dispensable member of the treatment team. Under these circumstances, the professional has three options.

1. He can reduce his cognitive dissonance by subscribing to traditional views. If he does this, he will eventually be accepted and find his circumstances increasingly comfortable.
2. He can attempt to use his professional training and perspective. His success will often be a function of his charisma, diplomacy, and the nature of the clinic. Often, he will find himself stymied by the passive—and sometimes active—resistance of the paraprofessional workers and those of his colleagues who have opted for tactic number 1.
3. He can flee to more comfortable and less divisive and frustrating clinical pastures (e.g., mental health). Those who choose to stay are likely to be the best and the worst (28).

PROBLEMS AND PARADOXES

Unfortunately, problems rooted in the very origin and structure of an institution are not likely to yield to

simple or painless solutions. The problems and conflicts we have discussed are deeply rooted in the history, dogma, and constituency of the alcoholism treatment enterprise. Each conceivable pragmatic revisionist strategy carries with it a paradox.

If through some administrative fiat empirical research findings were suddenly incorporated into clinical practice, a panoply of problems would result. First, it would be apparent that the vast majority of treatment personnel lack the training to apply innovative treatment methods. The paraprofessional's area of expertise would become obsolete: his credentials in the field (i.e., his personal experience) would no longer be marketable (29). The sudden shifts in power that would be produced by the application of treatment procedures and philosophies unfamiliar to the paraprofessional but within the area of expertise claimed by the professional could present an even greater problem.

We envision yet another Pandora's box of complications if the clinical field were somehow made more tolerant of healthy controversy, more responsive to empirical findings, and more receptive to new methodologies.

It is not unlikely that a training and orientation program that would inevitably tend to "professionalize" the paraprofessional would produce massive resistance, conflict, and upheaval. The process of professionalization, of increasing the paraprofessional's clinical sophistication and versatility, would produce a crisis of commitment by threatening the underlying antiprofessionalism that binds these workers to the organizational structure and validates their beliefs. Pattison warns that "A self-help group should not be professionalized or scientificized, because that would undercut the very socio-psychological matrix that makes a self-help group effective" (14, p.620).

The alcoholism treatment enterprise now finds itself in a Procrustean dilemma—to eschew the empirical, scientific orientation for the sake of intramural tranquility and therefore abandon alcohology as a scientifically oriented clinical enterprise, or to adopt the classical professional-scientific model and risk the alienation of a large segment of current treatment personnel. Ignoring this dilemma, as was done in the past, is no longer an option and would only cause further alienation and dissension within the field and even more confusion in the public about the nature of alcoholism. The alcoholism treatment field can no longer masquerade its craftlike organization under the banner of science.

Until this decision is made, no amount of funding, training, recruitment, or bureaucratic reorganization will materially alter the impact of the alcoholism treatment system. As Ludwig notes, the promise of the alcohol system "will not be realized by having more money, more staff, and more facilities but rather by qualitative changes in the nature of the activities conducted, a willingness to admit to relative scientific ignorance and a concerted effort to remedy these deficits" (18, p.156).

Clinical Response and Plasma Levels: Effect of Dose, Dosage Schedules, and Drug Interactions on Plasma Chlorpromazine Levels

BY LEONOR RIVERA-CALIMLIM, M.D., HENRY NASRALLAH, M.D., JOHN STRAUSS, M.D., AND LOUIS LASAGNA, M.D.

Plasma chlorpromazine (CPZ) levels of 50 psychotic inpatients were measured by gas liquid chromatography; the clinical progress of 29 of these patients with acute psychoses was also assessed. CPZ levels of 50–300 ng/ml were usually associated with clinical improvement; there was also a relationship between CPZ levels and increases in certain symptoms. The 50–300 ng/ml level was best attained by doses of 400–800 mg/day. Trihexyphenidyl decreased plasma CPZ by a mean of 44.7% in 12 of 15 patients. A single 400–800-mg dose of CPZ at bedtime produced steady states equal to or better than those achieved with multiple doses. Those patients who failed to attain CPZ levels of more than 70 ng/ml despite doses of 400–1000 mg/day were receiving lithium throughout the study and had discharge diagnoses of manic-depressive psychosis, manic type, and schizo-affective schizophrenia—a finding with implications for future research.

PHENOTHIAZINES are the most effective and widely used antipsychotics despite the variable and unpredictable clinical response of psychiatric patients to these drugs. With the advent of sensitive assays for plasma chlorpromazine (CPZ), attempts have been made to correlate plasma levels with clinical improvement.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

The authors are with the University of Rochester School of Medicine and Dentistry, Rochester, N.Y. 14642, where Dr. Rivera-Calimlim is Associate Professor of Pharmacology and Toxicology, Dr. Nasrallah was a resident and fellow, Department of Psychiatry (he is now a Fellow at the National Institute of Mental Health), Dr. Strauss is Associate Professor of Psychiatry, and Dr. Lasagna is Professor of Pharmacology and Toxicology.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-24188 from the National Institute of Mental Health.

Smith Kline & French Laboratories, Philadelphia, Pa., supplied standard chlorpromazine, and Dr. Albert H. Maniam, National Institute of Mental Health, supplied chlorpromazine metabolites.

The authors wish to thank Alan Siracusa for technical assistance, Drs. H. Babigian, R. Linares, and P. Ruggero, Rochester Psychiatric Center, for their help, and Dr. Monte-Verde, Strong Memorial Hospital, for the services of the phlebotomist.

Recent observations by Rivera-Calimlim and associates (1) suggest that there may be some correlation between plasma CPZ levels and both clinical improvement and toxicity. These investigators found that patients who did not improve clinically (as assessed by the Brief Psychiatric Rating Scale) generally showed very low plasma CPZ levels (less than 30 ng/ml). Those who did improve generally had plasma levels ranging from 150 to 300 ng/ml. Patients with extrapyramidal signs and convulsions had plasma levels ranging from 700 to 1000 ng/ml and more.

There were, however, some patients whose BPRS scores improved despite low plasma levels, and others who failed to improve despite adequate plasma levels. We attempted to improve the sensitivity of the BPRS by stratifying its items into four subgroups—thought disorders, paranoid behavior, anxious depression, and withdrawal-retardation. In the present study we examined correlations between responses in the various subgroups and plasma CPZ levels. We also investigated the effects of dose, dosage schedule, and drug interactions.

METHOD

The study was carried out by members of the Department of Pharmacology and Toxicology and the Department of Psychiatry at Strong Memorial Hospital and Rochester Psychiatric Center. The significance of plasma CPZ levels in acute and chronic psychotic inpatients was investigated. The clinical pharmacologist responsible for the assay of plasma CPZ had no access to the clinical records of the patients, and the rating psychiatrist did not know the plasma levels or the mode of management being used for the patient. Clinical evaluation was done only for patients with the diagnosis of acute schizophrenia. The effects of dose, dosage schedule, and drug interaction were studied in both acute and chronic patients.

Subjects

The criteria for the selection of subjects included 1) written informed consent signed by the patient or nearest relative, 2) estimated hospital stay of 3–6 weeks, 3) absence of gastrointestinal, urinary, or liver disease,

and 4) the patient's need for CPZ, either alone or with adjunctive treatment, as determined by the attending physician. The acute patients ranged in age from 18 to 37 years and the chronic patients from 40 to 65 years. There was a total of 50 subjects, 21 with diagnoses of chronic psychosis and 29 with acute psychoses.

Assay and Assessment

Plasma CPZ was assayed by the gas liquid chromatography (electron capture detector) technique of Curry (2), modified by Rivera-Calimlim and associates (1).

Response to drug therapy was measured by the BPRS, a 16-item scale of signs and symptoms. Ratings range from 0 (not present) to 6 (extremely severe). Stratification of the 16 items into the subgroups of thought disorder, anxious depression, paranoid behavior, and withdrawal-retardation was done by the method of Overall and associates (3).

The rating scale was scored by the patient's therapist and by one of the investigators (H.N.). Interrater reliability of the BPRS items, assessed by product-moment correlation, was acceptable for 11 items ($r=.70$, $p\leq.002$) and for the total BPRS score ($r=.83$, $p<.001$), moderate but still highly significant for 4 items (conceptual disorganization, guilt feelings, mannerisms and posturing, and blunted affect) ($r\geq.50$, $p=.03$), and unacceptably low for 1 item (depressive mood). We decided that validity could be maximized in the data analysis by averaging raters' scores for the patients. The lower reliability of some items would have the effect of underestimating relationships between the symptoms they reflected and CPZ levels and therefore would err on the conservative side, reducing the chance of spurious correlations.

Procedure

On the day of admission to the study, the clinical condition of the 29 patients with acute psychoses was assessed by the BPRS and blood samples were drawn from all patients for measurement of baseline values of plasma CPZ.

Dose, dosage form, and dosage schedule were left to the discretion of the attending physician, with the agreement that 400 mg/day was the lowest dose to be used and that changes in doses should not be made more than once a week (stabilization of plasma CPZ is assumed to take about a week). The effect on plasma CPZ of addition and withdrawal of trihexyphenidyl was monitored, allowing 1–2 weeks after any change of treatment for stabilization. Plasma levels at 7:00 a.m. and 6:00 p.m. of patients receiving divided doses of CPZ (at 8:00 a.m., 2:00 p.m., 4:00 p.m., and 7:00 p.m.) were compared with plasma levels of patients receiving an equivalent amount of CPZ in a single dose at 7:00 p.m. Within-subjects comparison was done for a few patients, who were given divided doses for 2 weeks and then single doses for another 2 weeks. Assay of the plasma CPZ was done 1 day each week at 7:00 a.m. and 7:00 p.m. for each patient.

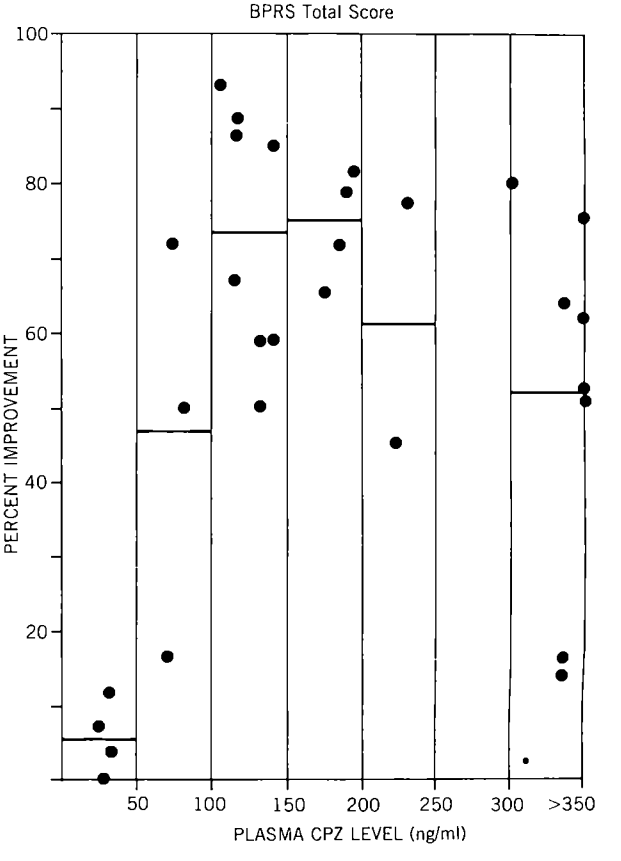
Plasma CPZ levels were assayed and the BPRS was administered weekly for 3–4 weeks. Blood samples were collected before (predose level) and 2, 3, and 4 hours after the first morning dose. Patients fasted (except for water) from midnight until the end of the blood collection. Treatment records, BPRS scores, and plasma CPZ levels were matched and analyzed to assess 1) the relationship between change in clinical status and plasma CPZ levels, and 2) the effect of dose, dosage schedule, and drug interactions on plasma levels.

RESULTS

Figures 1–5 show the relationship between clinical improvement and plasma CPZ levels, expressed as the average of 3–4 weekly determinations (allowing 1 week for plasma stabilization). (Horizontal lines within each range represent the mean for patients who fall within that range.)

Figure 1 shows the distribution of plasma CPZ levels plotted against the percentage of clinical improvement as measured by the total BPRS score (change from baseline score to the score at the end of 3–4 weeks).

FIGURE 1
Percentage Global BPRS Improvement as a Function of Plasma CPZ Level



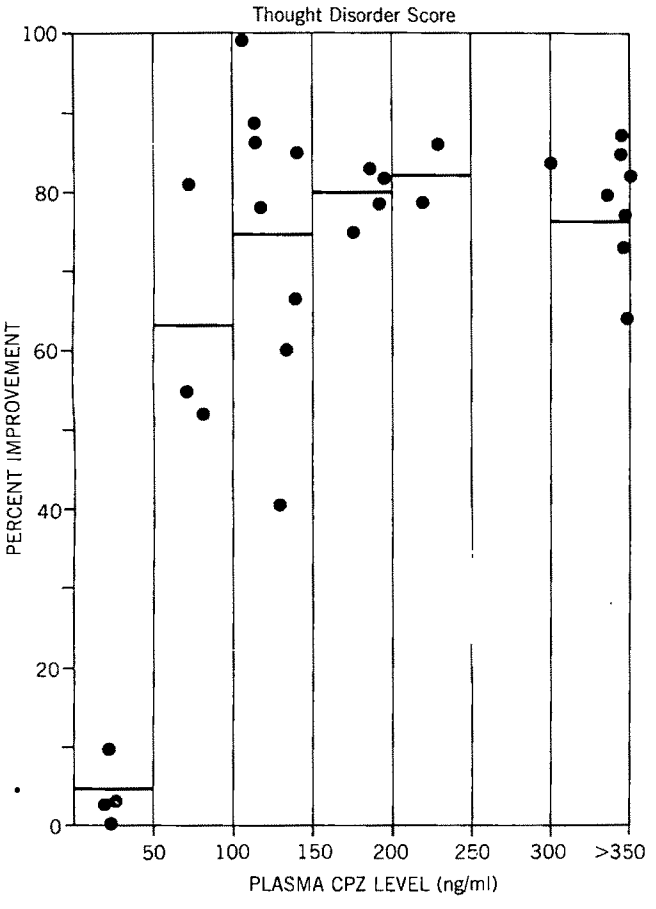


FIGURE 2
Percentage Improvement on BPRS Thought Disorder Score As a Function of Plasma CPZ Level

The 4 patients with plasma levels below 50 ng/ml showed a mean improvement of 5%. Two of the 3 patients who achieved plasma CPZ levels of 50–100 ng/ml showed improvement of 50% to 70%; the third patient had only 16% improvement. Twelve patients who achieved plasma levels of 100–200 ng/ml had a mean clinical improvement of 74%. The mean clinical improvement of the 8 patients with plasma levels of 300–500 ng/ml was lower than that of the 12 patients with levels of 100–200 ng/ml. The records indicated that the patients with the highest plasma levels had more severe baseline symptoms, which apparently necessitated larger doses of CPZ.

Figure 2 shows a clear association between plasma levels and percentage improvement on the BPRS thought disorder score. The 4 patients who did not achieve plasma CPZ levels higher than 30 ng/ml did not improve. Of the 25 patients who achieved levels above 50 ng/ml, 24 showed improvement of 50% to 82%; the 25th showed 40% improvement. As Figure 3 shows, improvement in paranoid delusions also seems to be associated with plasma CPZ levels, but the variation in paranoid delusion ratings is much greater. Figures 4 and 5 reveal no correlation between changes in depression and withdrawal-retardation and plasma CPZ levels.

Table 1 shows the plasma CPZ levels of patients on different daily doses. The results indicate a poor correlation between dose and plasma levels. Although the 3 subjects who achieved the highest levels (patients 10, 11, and 15) received relatively high doses, some patients on very high doses achieved very low plasma levels. Patients given a 400-mg daily dose achieved plasma levels comparable to some of the patients given substantially higher doses. It is interesting to note that plasma CPZ levels during the 4 hours after the dose tended to show a plateau—only patients 7, 8, 16, and 18 showed peaks in plasma CPZ levels.

Table 2 shows the morning and evening plasma CPZ levels in patients on single- and divided-dose schedules given comparable total daily dosages. Patients who were given 400–600 mg daily as a single dose in the evening achieved plasma CPZ levels of 66–264 ng/ml 12 hours after receiving their medication. Their plasma levels dropped by 12% to 50% between the 12-hour and 23-hour samples. Patients given divided doses achieved much lower plasma levels in both the morning and the evening assay than those receiving a single evening dose.

10	538	345	(−) 36
11	119	32	(−) 74
12	51	0	(−) 100
13	132	170	(+) 36
14	100	242	(+) 142
15	48	77	(+) 60

* Plasma levels were taken after 2 weeks without trihexyphenidyl and then after 2 weeks with trihexyphenidyl. Levels are expressed as steady state for the particular treatment condition. The trihexyphenidyl dosage was 2 mg three times a day.
** Changes are expressed as percent change from baseline plasma levels; (−) indicates a decrease, (+) an increase.

Table 3 shows the plasma levels of 15 patients who were on CPZ for the first 2 weeks without trihexyphenidyl (Artane) and were then given 2 mg of trihexyphenidyl three times daily for the second 2 weeks in conjunction with CPZ. After the addition of trihexyphenidyl, there was a drop in plasma levels ranging from 6% to 100% in 12 of these 15 patients. To assess the importance of order effects, 4 patients were placed on CPZ and trihexyphenidyl for the first 2 weeks and trihexyphenidyl was withdrawn during the next 2 weeks of CPZ treatment. Table 4 shows that there was an increase ranging from 7% to 318% in plasma CPZ levels after withdrawal of trihexyphenidyl.

FIGURE 3
Percentage Improvement on BPRS Paranoid Delusion Score as a Function of Plasma CPZ Level

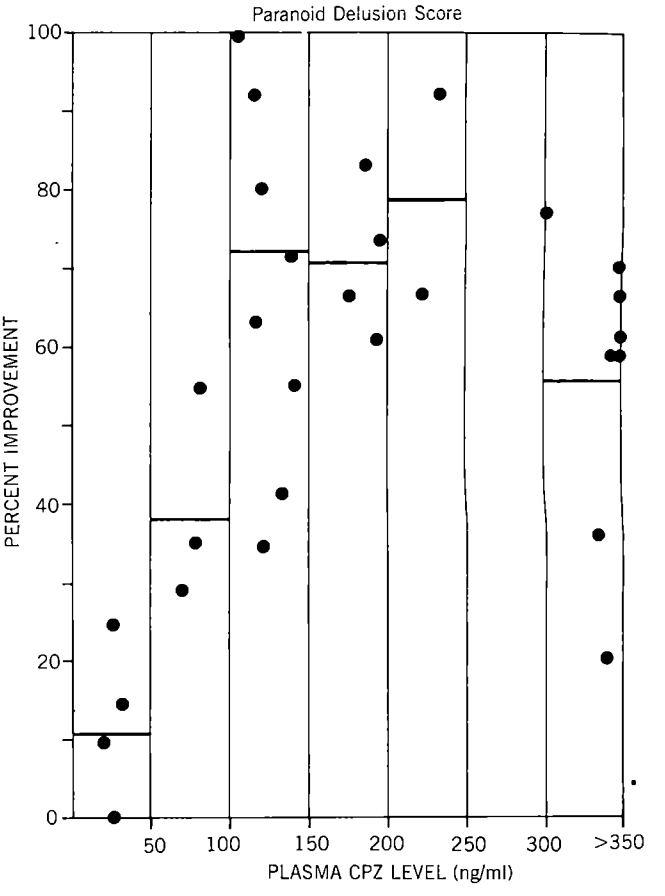

TABLE 4
Effects of Withdrawal of Trihexyphenidyl on Plasma CPZ Levels

Patient	Plasma CPZ (ng/ml)* With Trihexyphenidyl	Without Trihexyphenidyl	Percent Change**

Percentage Improvement on BPRS Withdrawal-Retardation Score as a Function of Plasma CPZ Level

DISCUSSION

This study has attempted to substantiate pharmacologically some aspects of phenothiazine therapy that have been accepted for many years on the basis of clinical findings alone. Studies involving thousands of patients during the sixties (4–9) showed that phenothiazine administration produced significant clinical improvement in acute schizophrenics. Clinical relapse is far more frequent in patients for whom phenothiazines are withdrawn than in those who continue on these medications (10, 11).

The findings of this study show that some degree of clinical improvement, based on the global BPRS score, is generally associated with plasma CPZ levels of 50–300 ng/ml, as was found in a previous study in our laboratory (1). When the BPRS score was broken down into four component dimensions, the 50–300 ng/ml range in CPZ level was clearly associated with improvement in thought disorder and reasonably well associated with improvement in paranoid behavior, but there was no correlation between plasma CPZ levels and clinical improvement in depression or withdrawal-retardation. Worsening of blunted affect, motor retardation, somatic concerns, and uncooperativeness was found in several patients, especially those with very high plasma levels (700–1000 ng/ml). These data suggest that studies designed to clarify the relationships between plasma levels and clinical improvement must assess specific endpoints such as symptom groups, as well as overall changes. Evaluating clinical improvement only in a global fashion may mask either beneficial or adverse effects of the drug. Such masking may obscure the ways in which a drug has helped the patient or the possibility that adverse effects may contribute to patients' discontinuing their medication.

Clinical assessment in psychiatry is made particularly difficult by the lack of objective endpoints (e.g., blood pressure, uric acid levels, cholesterol levels, or urine output) and the extreme variation in the treatment goals of individual psychiatrists. Because of this, it is especially difficult to set rules for optimal plasma levels of CPZ or any psychotropic drug. Nevertheless, we tried to determine whether our findings suggested clinically optimal plasma levels of CPZ in the treatment of acutely psychotic patients.

Our results suggest that 400 mg daily is a good starting dose for acute schizophrenics. The data in table 1

suggest that a 400-mg dose often achieves plasma levels comparable to those found with higher doses. There is only a limited correlation between dose and plasma levels, however, so that dosage increases may be required when patients fail to improve or to achieve plasma levels of at least 50 ng/ml.

Several clinical studies have shown that therapeutic outcome does not seem to differ on the basis of single-dose versus multiple-dose schedules of antipsychotic medication (12–16). We measured the morning and evening plasma levels in patients on both schedules, and our results suggest that the single-dose regimen gives more consistent levels throughout the day. Patients who were given a single dose at night showed reasonable plasma levels even after 23 hours. The patients on multiple-dose schedules who achieved adequate plasma levels were those who received additional doses of 200–500 mg at night. Patients who were not given these additional evening doses had low plasma CPZ levels at 7:00 a.m. before the morning dose. It appears from this study that CPZ plasma kinetics may be dose dependent. Even if a single daily dose is given, 35% to 40% of it is distributed and bound in the gastrointestinal tract wall (17). Thus the gastrointestinal tract may act as a buffer to sudden increases in dosage and serve as a depot for the CPZ.

If our findings on plasma levels and dose regimen can be replicated and the superiority of the single dose regimen is confirmed, it will help patients take their medication more consistently, lessen nurses' workloads, and limit the sedative action of CPZ to nighttime, when it is beneficial (or at least not unpleasant).

Our data suggest an adverse effect on plasma CPZ levels of concomitant administration of trihexyphenidyl, an anticholinergic drug often used to combat parkinsonian side effects. In recent years the prophylactic or prolonged use of antiparkinsonian medication in patients receiving phenothiazines has been branded as needless (18–20). Twelve of our patients who had trihexyphenidyl added to the treatment regimen showed a drop of 6% to 100% (mean=44.7%) in plasma CPZ levels. When trihexyphenidyl was withdrawn from 4 patients who had already received it for 2 weeks, the plasma CPZ levels increased.

Thus, trihexyphenidyl (and conceivably other anticholinergic agents) seems to produce a decrease in plasma CPZ. Animal research in our laboratory has shown that trihexyphenidyl slows stomach emptying, thus interfering with the absorption of CPZ (21). Hence unnecessary use of antiparkinsonian medication not only may be economically unwise and cause side effects but also may result in wastage of a significant portion of the CPZ dose in the gastrointestinal tract and possibly compromise the therapeutic effect of CPZ, especially in patients with minimal plasma levels. The anticholinergics probably exert their antiparkinsonian effect at least partly by reducing the level of CPZ in plasma, which is more logically and economically achieved by reducing the dose of CPZ.

Another finding of potential significance concerns the 6 acutely psychotic patients (out of a total of 29) who had low plasma levels, ranging from 0 to 76 ng/ml, despite adequate dosage (400–1000 mg/day). These patients were the only ones who received lithium throughout the study (900–2400 mg/day). Of these 6, 4 had a discharge diagnosis of manic-depressive psychosis, manic type, and 2 had a discharge diagnosis of schizo-affective schizophrenia, excited type.

There are at least two possible explanations for this finding. Lithium may interfere with the absorption, accelerate the metabolism, or increase the excretion of CPZ, or patients in an excited, manic, or maniclike state may absorb CPZ poorly, metabolize it quickly, or excrete it rapidly. Some support for the latter hypothesis is provided by the common clinical observation that manic patients and excited schizophrenics often require huge doses of CPZ before showing a tranquilizing effect. Both of these possibilities present exciting areas for further research.

American Board of Psychiatry and Neurology Forms Joint Steering Committee on Recertification

The American Board of Psychiatry and Neurology has formed a Joint Steering Committee on Recertification. At its first meeting in Kansas City on February 19, the committee established four subcommittees, which will report to the full steering committee at a meeting to be held in Philadelphia July 14, 1976. At this time the group will initiate plans for a national conference on continuing clinical competence and the related issue of recertification, to be held some time in 1977. The four subcommittee areas are: communications and relationship to the profession, forms of testing, curriculum content of continuing education, and administrative and legal questions.

Richard I. Shader, M.D., and Robert Senescu, M.D., were appointed by President Judd Marmor to serve as APA's representatives on the joint steering committee. The other members of the committee represent the American Board of Psychiatry and Neurology, the American Neurological Association, the American Academy of Neurology, the Child Neurology Society, and the American Academy of Child Psychiatry. The idea for the joint steering committee arose through the ABPN, which as a first step appointed an ad hoc committee. This committee held a planning meeting in Kansas City, Kansas, in October 1975, at which time it recommended that the major psychiatric and neurological organizations be invited to appoint members to a steering committee.

Can Psychiatry Police Itself Effectively? The Experience of One District Branch

BY ARTHUR ZITRIN, M.D., AND HENRIETTE KLEIN, M.D.

The growing demand by consumers and government for greater accountability from psychiatry is challenging the traditional system of self-policing by which the profession's standards of ethical conduct are established and maintained. The authors describe the operations of a district branch ethics committee, including types of complaints received, investigatory procedures, disposition of cases, and factors limiting the committee's effectiveness. They conclude that in some cases lack of funds, lack of time, and the use of peers to judge alleged misconduct make unbiased and thorough evaluation of complaints difficult. They suggest that psychiatry must take steps to improve public confidence in its ability to police itself so that the power to regulate professional conduct will remain within the profession.

MEDICINE in the United States has traditionally been largely self-policed. Society has permitted the profession to establish standards of ethical behavior and norms for quality of medical care; adherence to these standards is monitored principally by medical societies, hospital boards, and committees of professional organizations.

A recent comprehensive review by Derbyshire (1) of organized medicine's disciplinary functions concluded that they were not adequate. He also found that state boards of medical examiners were lax in carrying out regulatory duties, and warned that control of medical discipline might be taken away from the profession unless all agencies involved improved their methods and performance.

Psychiatry is subject to the same procedures and regulations with regard to ethical practice that govern other branches of medicine. *The Principles of Medical Ethics* of the American Medical Association were recently annotated by APA (2) to give them greater usefulness as guides to the acceptable practice of psychiatry. The annotations were formulated to take into account "the special ethical problems in psychiatric practice that differ in coloring and degree from ethical problems in other branches of medical practice" (2).

Data reported at a meeting in May 1974 of the APA Ethics Committee with representatives of the ethics committees of all district branches suggested that the self-policing activities of psychiatry are probably no more effective than those of the rest of medicine. Some district branches have no ethics committee; others have committees that function only as advisory bodies for local medical societies. Local procedures for investigating complaints vary. The use of legal counsel does not appear to be routine.

The recently established policy of reporting all local complaints to the APA Central Office is not uniformly followed, so it is impossible to state with precision the number of complaints received nationwide during a given period. In the year from May 1973 to May 1974, a total of 61 notices about complaints of alleged unethical conduct was sent to APA by the district branches. Sections 1, 4, and 9 of the *Principles of Medical Ethics* (2) were alleged to be violated most frequently (10, 28, and 8 complaints, respectively). These sections read as follows:

> *Section 1.* The principal objective of the medical profession is to render service to humanity with full respect for the dignity of man. Physicians should merit the confidence of patients entrusted to their care, rendering to each a full measure of service and devotion.
>
> *Section 4.* The medical profession should safeguard the public and itself against physicians deficient in moral character or professional competence. Physicians should observe all laws, uphold the dignity and honor of the profession and accept its self-imposed disciplines. They should expose, without hesitation, illegal or unethical conduct of fellow members of the profession.
>
> *Section 9.* A physician may not reveal the confidences entrusted to him in the course of medical attendance, or the deficiencies he may observe in the character of patients, unless he is required to do so by law or unless it becomes necessary in order to protect the welfare of the individual or of the community. (2, p. 1059)

Five complaints of alleged violations of section 3 were reported, 1 of section 5, 2 of section 6, 5 of section 7, and 2 of section 10; no complaints of violations of section 2 or section 8 were received.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Zitrin is Professor, Department of Psychiatry, New York University School of Medicine, 550 First Ave., New York, N.Y. 10016. Dr. Klein is Special Lecturer, Department of Psychiatry, Columbia University College of Physicians and Surgeons, New York, N.Y.

A DISTRICT BRANCH ETHICS COMMITTEE

This report is based on the experiences of one district branch over the past eight years. The branch currently has 1,535 members. Under the provisions of its constitution the Committee on Ethics and Discipline is composed of up to 10 members and is chaired by a past president of the branch.

The general scope of the committee's jurisdiction as set out in the branch's constitution includes "any alleged breach of the Constitution and By-Laws of the Society, or, activities or behavior alleged to be unprofessional. . . ." The language of the APA By-Laws is somewhat different; it refers to complaints "that a member has engaged in unethical conduct or has brought discredit or dishonor on the Association and/or the practice of psychiatry" (Chapter 10, Section 2, By-Laws, American Psychiatric Association).

Committee Procedures

In general, only written complaints about members are referred to the district branch's Committee on Ethics and Discipline, although matters that have come to the council's attention may be considered without a formal complaint. If the Ethics Committee as a whole feels that the alleged offense comes within its province, it refers the matter to an appointed subcommittee for exploration. In almost every case the psychiatrist about whom the complaint is made is interviewed, as is the complainant. It was felt that initial investigation by a small subcommittee would protect confidentiality, be responsive to the sensitivities of those interviewed, and facilitate an open dialogue. A final decision is made after a review of the subcommittee's findings by the entire committee. Occasionally documents are requested and/or other persons or agencies are contacted for relevant information. The Ethics Committee operates independently of disciplinary committees of the county and state medical societies and other local professional organizations.

The scope of the committee's investigatory power is not specified, and it relies wholly on the voluntary compliance of witnesses. So far in our experience no accused physician has refused to cooperate in an investigation or to meet with the Ethics Committee. In a number of instances, complainant and psychiatrist, on the recommendation of the investigating subcommittee, have met separately with the entire committee. Final committee recommendations on each case are submitted to the executive council of the district branch for approval. No final finding of unethical conduct can be made by the council without a full hearing, at which the accused person has the right to examine witnesses, produce witnesses for himself, and be represented by counsel. A vote for disciplinary action by the executive council can be appealed to the district branch membership.

An attorney specializing in psychiatry has been retained on an ad hoc basis to advise the Ethics Committee and the executive council.

Type of Complaints Received

During the period from 1970 to 1974, 44 complaints alleging improper conduct by district branch members were considered by the committee, four times as many as during the previous four years. A wide variety of offenses was charged; they can be grouped under the following headings, according to the major impropriety alleged.

Category 1: a miscellaneous category containing complaints of rudeness, suggestive sexual comments, inadequate time for examination, and delays in specific appointments (9 complaints).

Category 2: charges of undue influence, such as those relating to investments or marriage choice (6 complaints).

Category 3: alleged violations of the prohibition against sexual relations with patients (5 complaints).

Category 4: allegations about a doctor's lack of cooperation in filling out insurance forms or providing statements for tax purposes, including complaints that a doctor refused to send such forms until his bill was paid (3 complaints).

Category 5: complaints about improper advertising (3 complaints).

Category 6: complaints about excessive fees (3 complaints).

Category 7: charges of improper diagnosis resulting in loss of job (3 complaints).

There was a variety of other complaints, such as interference with ongoing psychotherapy by another psychiatrist, refusal to agree to consultation, physical assault, improper treatment, and excessive prescription of drugs.

The Ethics Committee voted for a finding of unethical conduct in only two instances. (In many other cases the committee felt the charges were justified but lacked sufficient proof to warrant a finding against the doctor.) In one case, the physician violated section 1 of the *Principles of Medical Ethics* by exerting undue influence on a patient. In the second case a physician who charged an excessive fee was found to be in violation of section 7.

Relatively few complaints were frivolous, malicious, or patently without merit. Many had been lodged only after considerable hesitation by the patient, or only after they had been urged to do so by a physician. In two cases the complainants were psychiatrists.

Difficulties Encountered by the Committee

The committee became aware quite early in the course of its work of a number of serious difficulties and ambiguities that often made discharge of its duties difficult and sometimes impossible. In several instances the accused physician was known to all members of the committee. In such cases, could the committee be viewed by the complainant and the charged psychiatrist as unbiased?

In some cases it was unclear whether a complaint came properly under the committee's jurisdiction. Was a matter of ethics involved, or a question of quality of medical care? How far could an ethics committee go in its investigation of a complaint? How much could it accomplish without a resource staff? There were a number of serious complaints in which additional evidence should have been sought, but this would have required time-consuming investigation that lack of staff precluded. In some cases patients had also filed civil suits against the physicians about whom they complained to the district branch. The advice of legal counsel was used to guide the committee on these matters.

The difficulty in determining precisely what takes place in the patient-psychiatrist encounter was underscored in cases in which the committee had to choose between two conflicting versions of a story, that of the patient and of the doctor. In one instance the committee members, all highly experienced psychiatrists and psychoanalysts, were divided as to where the truth lay. In this case a female patient accused her male physician of having had sexual relations with her over a long period of time. Lack of corroborating evidence precluded a definitive finding.

In general the committee was reluctant to widen investigations by referring complaints to legal or administrative governmental agencies. The criteria for doing so were unclear, and the district branch council never requested that the Division of Professional Conduct of the Department of Education (the state licensing and medical disciplining agency) conduct its own investigation of a complaint.

Although a clear and fair determination of whether unethical conduct had taken place was possible in most cases, in some instances no such certainty prevailed. Some members became increasingly uneasy in their committee role because they wondered whether the committee served merely as a buffer between the public and the profession, since it was without the resources, the objectivity, and (perhaps) the will to do more.

DISCUSSION

Today we are witnessing public demand for a more equitable distribution of health care, and government involvement in the delivery of such services is rapidly accelerating. Significant changes in public attitudes toward physicians are taking place. One authority on social policy and health services has warned that "the mystique that hitherto surrounded medicine is decaying, and there will be growing public support for public evaluation of the system as a whole, as well as its individual parts, and for the use of controls and sanctions" (3, p. 85).

This rise in "consumerism" is reflected by the increase in malpractice suits, the large settlements imposed by juries, and insistent demands for greater accountability of the medical profession. The nation's leading consumer advocate organization has concluded that medicine has failed to merit the public's trust that the profession will successfully regulate itself (4, p. 153).

What steps can psychiatry take to restore public confidence in its ability to police itself? The present arrangements for self-discipline will not long suffice; a system in which district branch committees attempt to monitor the actions of psychiatrists appears to be unrealistic and bound to fail. Small groups of busy volunteer psychiatrists without staff or funding cannot be expected to be investigators, prosecutors, judges, and juries in cases involving the reputations and professional careers of friends and acquaintances, even in a large psychiatric community such as ours. Even if they could do so, this system is unlikely to satisfy the demands of the rising consumer movement.

The most important factor ensuring ethical practice will always be the physician's own high standards of behavior and personal dedication to professionalism. The annotated *Principles of Medical Ethics* (2) remain excellent guidelines for psychiatric practice, and it may well be that their existence and the possibility of censure by peers are still strong deterrents to unprofessional conduct. However, additional peer review procedures need to be established if control over professional standards is not to pass out of the hands of the profession. The Professional Standards Review Organizations (PSROs) set up by section 249-F of Public Law 92-603 may well be the vehicle for a workable peer review system.

Recent reviews have commented on the difficulties of peer review in psychiatry (5–8), such as the inadequacy of psychiatric records, the limited usefulness of psychiatric diagnosis, variations in criteria for hospitalization and discharge, problems of confidentiality, and the complex nature of psychotherapy. As PSROs address these problems and formulate standards, they should also develop procedures for self-discipline that will overcome the shortcomings and failures of the present system.

Our district branch, through its Committee on Peer Review, has surveyed review practices in general hospitals in New York City and has developed some fundamental principles, methods, and strategies for peer review. The Committee on Peer Review also acts as a liaison to the PSRO conditionally designated by the Department of Health, Education, and Welfare for New York County. A joint committee composed of the chairpersons of the district branch committees on insurance, Medicaid, peer review, and ethics has recently been charged with coordinating the activities of these four groups.

It is likely that these new committees will develop more effective mechanisms for self-policing than now exist. More psychiatrists, particularly in hospitals, will soon have their professional work come under scrutiny by peer review bodies. However, unprofessional conduct will still be more difficult to deal with than professional incompetence. Reporting by physicians of un-

ethical conduct by colleagues is quite rare, and it will be difficult to provide incentives to alter this fact.

CONCLUSIONS

We believe that investigation of complaints against a physician should not be made by colleagues who know the accused, as is now often the case. The establishment of a statewide panel of psychiatrists, perhaps by the New York State Council of District Branches, would provide panelists who could investigate cases in cities other than their own. Staff and expense funds could be provided on an ad hoc basis. Although expensive and time-consuming, such a procedure would be a step toward demonstrating to the public the profession's willingness and determination to take care of its own house, and it might also help still demands for consumer participation in the policing procedure. What is now lacking is not a suitable definition of standards of professional psychiatric conduct but public confidence that psychiatry has the will to enforce these standards.

At this time in the history of psychiatry and the APA, with the current concern about organizational improvement and internal democratization, it seems as if the patient is sometimes forgotten. The goal of all our deliberations—about organization, training, research, and continuing education—must be improvement of the care of patients. Increased accountability, to ourselves and to the public, including better procedures for self-regulation, will be an important step toward that goal.

Cultural Perspectives on the Impact of Women's Changing Roles on Psychiatry

BY VIRGINIA ABERNETHY, PH.D.

The author examines sex role stereotypes in the United States and their impact on the self-concept of women. She suggests that the fact that women's roles are changing may have a positive impact on general mental health because both men and women will profit from increased flexibility in gender role specifications. She emphasizes the fact that therapists as well as their patients have been socialized into accepting the values and assumptions of our society; there is thus a high probability that not only the presenting complaints but also the treatment goals for women in therapy are culturally determined.

ALTHOUGH THE IDEAS of the women's movement are still difficult to understand and alien to many, the social pattern embodied in renewed agitation for women's rights can be seen as a fundamentally creative effort to innovate and grow that is in harmony with the underlying tenets of the mental health professions. The objectives of this paper are to show ways in which the new directions taken by women today are constructive and, in view of the charges of sexist bias that have been leveled against some mental health professionals, to suggest that the source of conflict is culture change rather than a war of patients against therapists or, still more destructive, women against men.

CULTURAL DETERMINISM

A premise of anthropology is that all of us are bound by our culture. The deeply held ideas, values, or beliefs of our society inevitably represent reality for us. This phenomenological sense of authenticity may be so great that we remain unconscious of the extent to which our cultural assumptions are mental constructs. Moreover, as long as we remain within a single stable culture our certainty of its assumptions is continually reinforced because culture is the shared contents of minds. Both therapists and patients are products of our culture; therefore, they are similarly determined, or bound, by our society's attitudes and behavior patterns.

Dr. Abernethy is Director, Division of Human Behavior, Department of Psychiatry, Vanderbilt University School of Medicine, Nashville, Tenn. 37232.

When there is no free choice, responsibility and recrimination are irrelevant. However, freedom from responsibility coupled with absence of free will is not a condition in which many might wish to remain. Just as psychoanalysis has the goal of exposing and thereby freeing an individual from the determinations of his or her developmental history, so an awareness of cultural forces can enlarge an individual's range of free choice.

Awareness of how women are constrained by our culture can be focused by considering sex role stereotypes. Research suggests that sex role stereotypes in our culture are pervasive, that they exert a major influence on self-concept and behavior, and that they may present an obstacle to the growth and mental health of both men and women (although they are more particularly damaging to women). Health care professionals necessarily share the stereotypes of their culture. Therefore, therapeutic goals are sometimes limited by culture-bound preconceptions of what is ideal or adaptive male or female behavior.

SEX ROLE STEREOTYPES

A number of research teams in the United States have reported congruent findings on ideas of what is archetypically male and female (1–5). Especially impressive is the work of Broverman and associates (6), who developed a sex role questionnaire consisting of 41 empirically derived items that distinguish between popular conceptions of the average man and the average woman at highly significant levels. Broverman and associates tested nearly 1,000 subjects in samples that covered a broad spectrum of religious, socioeconomic, sex, and age categories; they were consistently able to replicate their findings. The stereotypically masculine traits they identified clustered around the concept of competency; the stereotypically female traits clustered around the dimensions of warmth and expressiveness.

Social Desirability

The isolation of sex role stereotypes is in itself not so striking as Broverman and associates' discovery that the masculine cluster of attributes was more socially desirable than the female cluster: 29 of the 41 stereotypic traits at the masculine pole of the scale were judged to be not only more desirable but also more descriptive of a healthy adult; by comparison, only 12 of

the 41 traits at the feminine pole were judged to be more desirable and part of the healthy adult profile.

A sampling of the socially desirable items that clustered at the masculine pole follows: aggressive, independent, not emotional, hides emotions, objective, not easily influenced, dominant, active, competitive, logical, and worldly. The complete list of the socially desirable items that clustered at the feminine pole is as follows: doesn't use harsh language, talkative, tactful, gentle, aware of feelings of others, religious, interested in own appearance, neat, quiet, needs security, enjoys art and literature, and easily expresses tender feelings.

Self-Concept

The data of Broverman and associates further suggest that the skewed social desirability of the stereotypes impinges in a negative way on women's self-concept. Not only were there fewer positively valued feminine traits, but women, unlike men, appeared to incorporate the devalued characteristics attributed to their sex along with the positive characteristics. It appears that women saw themselves not only as sensitive, gentle, and expressive but also as subjective, easily influenced, passive, irrational, and not independent. Men, however, described themselves as possessing not only the positively valued competency attributes that were judged stereotypic for the average man, but also the traits of the feminine cluster that were positively valued for the average woman.

It is not known to what extent poor self-concept may be crippling. It seems a reasonable hypothesis, however, that a woman's internalization of a negative evaluation of female capabilities promotes her withdrawal from competition. This would then be a factor in the well-known tendency for girls' school performances to begin to deteriorate around high school age and in the associated downgrading of achievement goals among adolescent girls (2, 3).

Innate or Learned?

Justification for the stereotypes usually hinges on the protest that they represent the natural order and, therefore, nothing can be done. Thus it is necessary to confront a different order of question, i.e., whether the stereotypes are in fact an accurate reflection of male and female potentials independent of socialization pressure. In other words, are the differences between men and women innate or learned? Furthermore, if they are innate, do they exist in a small degree or in the magnitude suggested by the stereotypes?

Some assert that innate differences in any of the stereotypic traits must be negligible because observable variations within a sex are of greater magnitude than the difference between the averages of each sex, i.e., there is enormous overlap of male and female distributions. Clearly, the evidence that will resolve this hard question is not and may never be in. However, the facts that girls perform academically at least as well as boys up to the age when career choices begin to be made and that only after adolescence do discrepancies in male-female achievements favor the male (3) must present a problem for those who believe in innate differences in competence.

Similarly, statistics on the prevalence of various mental disorders in childhood show that boys greatly outnumber girls in every category, be it learning difficulties, behavior disorders, or childhood psychoses. However, among adults the prevalence of almost all categories of mental illness is reversed: women are sicker than men (4).

What causes this shift? Are adult, but not developing, women weaker than men? Is labeling applied differentially to men and women? Is the environment perhaps more pathogenic for women than for men? It is at least a plausible explanation of these related phenomena that the dawning realization of the culturally determined expectations for women and the choices closed to them causes young women to constrict their horizons, thus increasing their susceptibility to psychological disorders.

The issue of innate differences was directly addressed by Mead in *Sex and Temperament* (7), which described a New Guinea society in which women assume responsibility for the management and productive functions of the economy. These women exhibit characteristics associated with what our society judges to be competence to a greater degree than men, who are passive, narcissistic, and, to the extent that they dwell on jealous intriguing for the women's attentions, could be seen as masochistic. These findings suggest that differences between men and women along the specific dimensions of our cultural stereotypes are not so great as to be immutable. Role reversal is possible.

Finally, although ongoing investigation of innate male and female behavior is identifying some differences in predispositions between the sexes, these appear to be tangential to the stereotypic attributes. The apparent differences are that the male's activity level is higher (8, 9) and that from the embryonic stage onward the female's tolerance for stress is greater (10, 11). In addition, the cyclicity of female hormonal production probably exaggerates and inhibits certain traits in a rhythmic way; there is some evidence that there is an increase in sexual drive and in sense of competence and well-being around the time of ovulation (9, 12, 13).

The feminist position is that the issue of innate differences is a red herring. Because it is indubitably true that socialization accounts for at least some of the differences between male and female personalities, is it not a truer form of justice and a straighter road to mental health to endeavor to equalize the self-concept, training, and opportunities available to men and women (5, 14, 15)?

PSYCHOTHERAPEUTIC PRACTICE

The evidence is mixed as to whether the average mental health professional provides constructive and

appropriate support to female patients. The findings of Haan and Livson (5) suggest that female therapists are more critical of close adherence to sexual stereotypes by either male or female patients but that male therapists are more concerned by deviance from sexual stereotypes. However, other data (6) suggest that both male and female therapists evaluate patients against an idealization of these stereotypes.

The Broverman team (6) found not only that male and female mental health professionals agreed with each other on descriptions of characteristic differences between men and women but also that a comparison of clinicians' profiles of the average man and the average woman revealed a negative evaluation of the female character:

> The clinicians' ratings of a healthy adult and a healthy man did not differ from each other. However, a significant difference did exist between the ratings of the healthy adult and the healthy woman. Our hypothesis that a double standard of health exists for men and women was thus confirmed: the general standard of health (adult, sex-unspecified) is actually applied to men only, while healthy women are perceived as significantly *less* healthy by adult standards. (p. 71)

From these data it appears that some clinicians share the general cultural sex role stereotypes. The further inference is that these stereotypes color their perception of patients, their clinical judgments about prognosis, and, most vitally, their interactions with female patients. The net effect is probably that they promote women patients' choosing the traditional female roles and self-concept. The less healthy aspects of the feminine personality may be reinforced because so much of what is healthy is considered to be specifically masculine. It is difficult to allay the suspicion that in therapy just as in the culture generally a woman is rewarded for unaggressiveness, irrationality, dependence, passivity, and emotionality and that she may be attacked for exhibiting the opposite traits, which are judged by clinicians to be healthy in the socially competent adult person.

There are limits to inferences that can be drawn from therapists' responses to questionnaires or to hypothetical patient profiles. Clinical evidence that treatment varies systematically with the sex of therapist and patient is usually anecdotal. However, those who wish to be sensitized to this area of physician-patient interaction will find documentation in Asher's report on the American Psychological Association's casebook on sex bias and sex role stereotyping in psychotherapeutic practice (14).

According to Asher (14), patients' complaints focused on the male therapist's tendency to view women's problems in terms of unfeminine assertiveness, lack of compliance, inattentiveness to a husband's emotional requirements, and failure to put the needs of the marriage above personal satisfactions. The patient's career or aspirations may be depreciated, and the therapeutic goals might be set in terms of acceptance and adjustment to the roles of wife and mother. In addition, a woman's assertiveness is not infrequently interpreted as penis envy, and her attitudes toward childbearing or child rearing may be used as indices of emotional maturity.

THE RELEVANCE OF PSYCHOTHERAPY

Value judgments based on our society's traditional view of men and women carry a therapist a vast distance from the currents of the present cultural trend, which is gradually legitimizing a broad range of roles for women. Many women no longer docilely accept the idea that their psychological difficulties lie within themselves and that they must therefore strive to adapt to difficult environmental situations. Instead of trying to change themselves, their newly legitimized objective is to change or reject the difficult social environments (16).

Specifically, to view "feminine assertiveness as a neurotic phenomenon . . . aimed at overcompensation for and denial of the lack of a penis" (15, p. 90) is beginning to conflict with the ideas of our culture. On the contrary, large numbers of women accept the idea that women envy men for their social power and for the cultural permission given them to be competitive, rational, competent, and sometimes just plain ornery. Moreover, many women are asking why a mature woman should want a penis as part of her anatomy. Consider a contemporary feminist joke: A mother consoles her young daughter who feels outdone by a playmate's external anatomy, "Honey, with what you've got, you can get all you want of what he's got."

In order to be relevant to women today, therapists are asked to be creative, open, and nondirective. The fact that the therapist as an individual is a product of the traditional culture does not prevent him or her as a professional from recognizing that attitudes toward women have been culturally determined and do not necessarily represent truth. In the service of promoting mental health, a therapist can support a woman's endeavor to think and feel better about herself, to keep from becoming (in a self-fulfilling prophecy) a dependent, passive, and ineffective nonadult.

It should be recognized, however, that some women find that the best adjustment for them lies within the dependent stereotypic role model; increasing numbers, however, are questioning, distressed, or raging at the confines in which their lifestyle places them. The constructive therapist can provide support or insight for the change compatible with each patient's strengths and wishes.

In this context, it may be useful to repeat that many patients are as unaware as any traditional therapist that their treatment goals might be culturally prescribed and sex specific. Because of gender stereotyping, which until recently virtually all women accepted, both patient and therapist may misinterpret the

presenting complaints. Thus treatment may fall short of its potential to stimulate growth.

MARRIAGE AND FEMINISM

A further issue for the therapist is the impact of women's new attitudes and roles on a male-female relationship and, by extension, what the therapeutic goals for this dyad should be. This is an area in which there has been pessimism because of the prevailing view that a marriage necessarily suffers if a woman puts her own needs first. I wish to suggest on the contrary that the effect of the new trend is positive and that this will be increasingly evident as equality is more fully accepted and women are no longer pushed into positions of feminist militancy.

The basis for this healthier male-female relationship is that women who acquire social power for themselves in a career or professional setting are able to empathize in a new way with men who have always had this power and responsibility. Not only do the couple share new areas of common experience but the woman now has a sense of independence and competence and is therefore not threatened by the man's occasional needs to be passive, emotional, and taken care of.

The traditional culture denies men permission to express passivity and vulnerability. This is inevitable as long as husbands bear the sole responsibility for the security of dependent, stereotypically feminine wives. The artificial and rigid rules for masculine behavior can relax, however, as new rules for feminine behavior apply. A reprieve for women is a reprieve for men because as the culture comes to allow women greater scope for exercise of competence men will benefit from a complementary permission to be more expressive and less determinedly, exhaustingly invulnerable (16).

The prediction that male and female stereotypes will become increasingly blurred, to the benefit of both men and women, does not carry the implication that there will be role reversal in intimate dyadic relationships. Logically, it should be clear that for a woman to have an independent power base because of her societal role in no way determines the balance of power between her and any particular man: an increase in the overall competence and independence of women carries no intrinsic threat to male control of individual intimate relationships.

There is no evidence that a marriage is well served by the husband's being the weaker partner, but there is evidence to the contrary (17). Some have speculated that a cause of the currently high divorce rate is that as the traditional marriage develops, the woman becomes the more powerful personality. This imbalance occurs because of the cultural obstacles put in the way of a young woman's realizing her potential at a reasonable age. In the present pattern, a woman limits her self-concept and marries what seems to be a paragon of strength relative to her culturally prescribed weakness; the woman's later, unanticipated growth upsets the balance of the marriage.

I suggest that the trend should be toward more careful mate selection and that marriage should be delayed until both men and women have found occupational identities for themselves and have come to terms with who they are and can be. It is worth noting, in this context, that fostering achievement goals in young women is compatible with delayed marriage. Indeed, it might be sufficient cause for development of a delayed marriage pattern.

CONCLUSIONS

There is inherent contradiction in a health care tradition that systematically forces women into a stereotypic role that is judged by both clinicians and public opinion to be inferior to a healthy adult level of functioning.

It also appears that our culture is changing: new expectations, behaviors, and choices are opening to women. If the medical and mental health professions are to remain relevant, they need to be open in dealing with the changes. Conflicts and problems will inevitably arise; the opportunity for creativity lies in viewing these as manifestations of culture change rather than as the wrongheadedness of men or women.

The greatest challenge and field for innovation may lie in developing a model for marriage that is habitable by two fully adult persons. Men as well as women can derive greater satisfaction from a marriage in which both partners are allowed a full range of human expression—from competence and rationality to passivity and tenderness. Both men and women are, by turns, tough and soft. By accepting these needs in each other, they can be friends.

Therapists are participants in and products of their culture. Therefore, when the evolution in sex roles is completed, that transition will have been made in the mental health professions as well. However, why proceed in lockstep with the culture? By understanding the forces that shape our minds it is possible to be objective about the different and conflicting currents that are swirling around us today and to use our knowledge and self-knowledge creatively.

Journal Policy on Multiple Authorship

It has come to our attention that there has been some misunderstanding regarding the *Journal*'s policy on polyauthorship. The number of authors listed on a paper is not a factor in the review and acceptance/rejection procedure. However, once a decision has been made to publish a paper, we do apply *Journal* policy regarding the number of authors in the by-line: only principal researchers and writers of articles are listed in the by-line; collaborators who have provided technical and other assistance are acknowledged in a footnote. In papers that list more than 4 people as principal authors, we query the first author to verify that those individuals were substantial contributors to the research or ideas reported. Since certain types of psychiatric research may require multiple workers, we will of course include all of the names in these cases.

The Behavior of Hypersexual Delinquent Girls

BY JEROME D. GOODMAN, M.D.

The author presents case reports of seven girls with histories of hypersexual behavior associated with delinquency, aggressive behavior, and hypomania. Six of the girls had been exposed to virilizing hormones in utero or in childhood. Most of the girls in the sample were hirsute, tended toward mesomorphic build, and had been young at menarche. The author postulates that exposure to virilizing hormones can result in the kind of hypersexuality and delinquent behavior observed in his sample; he points out the need for adequate medical attention to this type of patient.

THE ASSOCIATION of problematic sexual behavior and juvenile delinquency in adolescent girls is commonly seen in juvenile courts. The pathway to the court for girls has traditionally involved charges of incorrigibility and running away, both of which carry implications of sexual behavior beyond parental sanction. Characterizing such sexual behavior as nurture-seeking rather than mature sexuality, Russell (1) found that the behavior of these girls had largely been allowed to run a chronic course before legal action was considered. Gianturco (2) has described problem sexual behavior in girls who had high scores on the Minnesota Multiphasic Personality Inventory scales for psychopathic deviate and hypomania.

Part of the upsurge in problem sexual behavior among adolescent girls is culturally related; contraceptives are more available now than formerly and there is greater acceptance of sexual behavior. Commenting on the changes in the sexual behavior of adolescents in the 1960s, Schmidt and Sigusch (3) cited as one factor the lower age at which the initial sexual experience takes place. There are probably biological determinants as well. The modern-day compression of childhood is a real phenomenon. The average age at menarche has dropped 3 or 4 years in the century since statistics have been recorded (4).

Early sexuality in adolescent girls can also reflect psychodynamic factors (5). Allen (6) described cases of hypersexuality as psychogenic in etiology. The surface appearance of hypersexuality, however, with a history of poor impulse control, rebellion against societal constraints and parental authority, and self-defeating patterns of promiscuity, does not preclude some true precocious priming or excess of libido. Freud, in discussing what he termed a powerful masculinity complex wherein some young girls identify with a phallic mother or father, asked, "What can it be that decides in favor of this outcome?" He answered, "We can only suppose that it is a constitutional factor, a greater amount of activity, such as is ordinarily characteristic of a male." (7, p.594).

Studies and clinical observations over the last 20 years have supported the thesis that biological libido, that is, the driving sexual force, is directly correlated with androgen levels. As Stoller (8) has written "Libido is clearly not dependent on estrogens in women but is probably the result of minute amounts of androgens normally produced in the adrenals . . .." In the case of adrenocortical carcinoma, for example, women can become rapidly virilized, with sudden onset of increased libido (9). The administration of methandrostenolone, an anabolic agent with known virilizing potential, can also result in hypersexuality.

There are other possible determinants of very active sexual behavior in young women. Manic episodes are often associated with hypersexuality, as are hyperthyroidism, certain lesions of the central nervous system, and other physical abnormalities. It is also true that some quite sexually active young women simply represent one extreme on the bell-shaped curve of biological variation.

Over the last 7 years I have examined a large number of adolescents for the Court of Juvenile and Domestic Relations in northern New Jersey. In a combined private and hospital-based practice, I have seen more than 400 adolescent girls at the direction of the court. Of these, 7 girls presented histories of unusual hypersexuality associated with delinquent behavior. These 7 girls underwent psychiatric examination, complete psychological test batteries, and a social investigation by probation officers. All of them were later followed in psychotherapy. Table 1 summarizes the behavioral and physical characteristics of these girls.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

CASE REPORTS

Case 1. A 15-year-old girl was seen in emergency psychiatric interview because of her agitated condition. She had made two suicide attempts by slashing her arms, and she carried scars of the 13 sutures required to close the wounds. There had been brief psychiatric intervention previously, but the major therapeutic effort was directed toward environmental measures (e.g., change in educational programs, different housing, and monitoring her association with peers) and family counseling. This young girl admitted having used LSD, methamphetamine (Methedrine), and marijuana.

When first seen in psychiatric examination, the girl appeared older than her years. Her facial acne and hirsutism were masked with cosmetics. She spoke in an unbroken torrent, pouring out historical material with seeming unconcern for censorship. This unguarded outpouring was perhaps the most striking characteristic of the initial interview. She told many family secrets and stated that she had only recently learned that her mother and father were not married at the time of her birth. Her affect was euphoric and she spoke very rapidly in a hypomanic fashion. She told of disturbed family relationships and described both parents as alcoholics.

The girl told about the separation of her parents, which lasted from her infancy until she was 9 years old. During these early years she was influenced considerably by the attitudes of her maternal grandmother, with whom she was placed periodically. When she rejoined her parents at the age of 9, she had pubic and axillary hair and had begun to menstruate. When she was between the ages of 13 and 15 her father began to make sexual advances toward her, culminating in intercourse shortly before her first suicide attempt. She had welcomed these advances and considered the evening rendezvous a special bond with a father who had deserted her as an infant.

She found that her sexual longings were intense and began to seek outlets more frequently. Approximately 6 months before her first suicide attempt, when she was 14 and her father was becoming increasingly bold sexually, she started dating one boy in particular. She was aggressive in securing this boy's attention. In addition, she often attended dances to pick up boys, and would perform multiple fellatio in order to demonstrate that she could entice a large number of boys in rapid succession. She also had a short-lived homosexual affair in which she acted the part of the masculine tribade.

At this time her breasts—which had been full—began to regress in size. She began to envy other girls and was particularly attracted to their breasts. Her account of this included "riding up on top and finger banging" another, more passive girl. Her entire fantasy life, dreams, and many of her activities were devoted to proving herself as a female. She was concurrently battling with hirsutism, diminishing breast size, irregular menses, and other physical signs of dwindling femininity. As her physical femininity seemed to be deserting her, her libido increased, and she began to engage in sexual activities of a polymorphous, perverse nature. During the 2 years prior to the suicide attempt she was in counseling, but her parents, especially her father, did not follow through in any consistent plan of psychiatric treatment. The girl made both of her suicide attempts after arguments with her father. Both attempts involved lacerations inflicted by razor blade. The first took place in her home, the second in a women's rest room in a public park. Both were serious attempts involving arterial bleeding. In the second attempt, she was discovered by a young man who "had the nerve to show me his prick. . . . I tried to cut it off. . . . I really would have." After she had recuperated from the second suicide effort she became more rebellious, impulsive, and provocative. It was at this time that she was separated from her parents and surroundings.

This 15-year-old girl was initially very unpredictable. Her ego strength was variable. She used rapid-fire, intense language with coprolalic expressions woven into her vocabulary. She filled the first six sessions with sexual material. She seemed to enjoy any shock value she could create, relating almost as though she were a young man bragging of his unending conquests. Her mood fluctuated between euphoria and depres-

TABLE 2
Serial Laboratory Assay of a 15-Year-Old Girl with Hyperadrenocorticism

Substance	Time of Assay							
	Initially	First Month	Second Month	Third Month	Fourth Month	Fifth Month	Sixth Month	Seventh Month
17-Ketosteroids (mg/24 hours)	16.50	27.10	25.00	15.80	7.28	17.97	6.45	5.45

Prednisone (mg/day, orally)	—	—	7.50	7.50	5.00	—*	5.00	5.00

* The subject stopped taking prednisone during the fifth month.

sion. It was at this time that consultation for endocrinological studies was begun. The girl's long-winded descriptions of her sexual dreams and memories seemed nonending. She began bragging about clandestine meetings with young men in the early morning hours. Her grandmother brought the matter to the attention of the juvenile court, and the girl was hospitalized; this provided the opportunity for more intensive medical investigation. Sexual material continued to occupy most of the clinical hours at this time.

Endocrinologists and clinical pathologists diagnosed her condition as acquired adrenal hyperplasia. Serial laboratory determinations are summarized in table 2. After treatment with steroids, bioassay revealed the expected decrease in adrenal substances, including the androgenic substances testosterone and pregnanetriol. There was a noticeable change in her attitude and thought processes only a week or two after the onset of steroid therapy. She became much more interested in schoolwork and became "feminized" in that her vocabulary, interests, and entire manner of presenting herself were vastly softened. Her mood was generally elevated and sustained from the previous intermittent dysphoria. Over a period of 3 months she became more interested in personal grooming, grew her hair to nearly shoulder length, and began dating again. Her sexual drive moderated. She accepted probationary status and was compliant with the rules of probation. She was no longer driven to prove herself as aggressive and sexually desirable.

Then suddenly, and almost as before, she again became aggressive, rebellious, and very sexually active. She again spoke about sexual matters in a poorly modulated manner. Her aggression became prominent, both in physical fighting with peers and general rebelliousness in school. She began courting neighborhood boys and keeping surreptitious rendezvous. She began to engage in more daredevil activities and to use coprolalic expressions during the treatment sessions. This behavior continued for a period of 4 weeks; then she admitted that she was not taking the prescribed doses of steroids. When she returned to regular steroid maintenance therapy, her behavior once again changed dramatically. Eventually, almost all sexual material disappeared from the clinical sessions. Even her repetitive dreams of a violent and usually sexual nature again abated. She remained on steroid therapy, graduated from high school, and married at age 19. There had been no recurrence of the behavioral difficulties.

The girl's unauthorized cessation of steroid therapy had caused the reappearance of the biological drives of aggression and hypersexuality. This variant of congenital adrenal hyperplasia, which is often milder and appears later, is also termed "postpubertal adrenal virilism." Grayzel (10) noted that clinical signs vary according to the age when excessive androgens affect the target organs. Acne, poor breast development, and low voice are more common than a large clitoris or pronounced hirsutism.

Case 2. This 16-year-old girl was seen by court order because of her possession of marijuana and stolen identity cards. She had earlier come to the court's attention due to her runaway and assaultive behavior. Her early childhood had been characterized by precocity, with high energy levels and excellent school performance. She preferred to play with boys and was agile and athletic. She had an IQ of 147 when she was 10 years of age. During our study this patient scored a full-scale IQ of 120 and appeared indifferent to higher achievement. In her words, "I used to hear how smart I was, that I could do anything I wanted . . . and I guess I rebelled against all of that and started to play the ignorant game." The girl had been persistently enuretic until her menarche at age 11. Her sexual adventures began in earnest at age 13. At age 14 she made a serious suicide attempt by lacerating her arm.

She had identified with "bikers" (motorcycle clubs)

and varieties of "freaks" and had been seriously burned during a fight with another girl who was vying for her position as "the old lady" to one of the "bikers." Shoplifting had become a way of life for her, although she had only been apprehended once. She had held a series of jobs in gas stations as a mechanic and customarily dressed in men's clothing (overalls, hat, boots). Starting at age 15 she was employed as a go-go dancer on the weekends. She freely admitted that she was bisexual, and her sexual identity was fluid and adaptable to the circumstances. In her last shoplifting venture she stole a nutcracker, a wrench set, and a timer (auto repair equipment) from a large store. Safely outside with this equipment, she returned to steal a hair curler, lipstick, and eye liner and was apprehended. When later asked what possible meaning was underscored by this shoplifting incident, she could only reply, "They're better set up for busting chicks in the makeup department."

Her hypersexual behavior took the form of marathons, frequently involving casual meetings. She occasionally had group sex and often had sex with men she met while hitchhiking. In one case, two men "worked me over with vibrators and oils." She was proud of her ability to have multiple orgasms. In her initial interview, when asked what she would like changed about herself, she replied, "A cock would come in handy." She had had several lesbian encounters but had no real preference in variety or form of sexual activity. This patient's manner of relating included large gestures with the hands, some pressured speech, and what appeared to be candor. She thought "as a man" and felt driven to be the pursuer, the aggressor, the initiator of sexual encounters. Her speech was filled with active vernacular expressions; she said she was the one who would "get it on . . . rip it off . . . blow his mind . . . or ball that chick." Basically, she saw herself as a misfit who had to conceal her intelligence and deny her need for security.

Her only medication was an oral contraceptive that she had taken since she was 15 years old. With therapy, there was some improvement in her delinquent behavior but little change in her sexual orientation.

Case 3. This 16-year-old girl was seen at the direction of the court because of a history of running away and incorrigible behavior. The girl's mother had been given injections of "hormones" during the first trimester of pregnancy to combat the threat of miscarriage. In addition, as a 12-month-old infant the girl was given "hormone shots" because of her small size; after that, she was said to have grown rapidly. Both series of hormones were administered in Europe. In addition to being of small stature in early childhood, she was quite hirsute and required extensive electrolysis for cosmetic purposes. She was restricted and very overprotected by her parents. During puberty she engaged in frequent masturbation, which was psychically painful but irresistible. Menarche at age 11 was uneventful but was presaged by full breast development and hirsutism from the age of 9.

Dating began as surreptitious adventures when she was 12. She saw older boys, and at age 14 began to run away with men in their twenties. She regarded sexuality as repugnant and anxiety provoking, but also as an irresistible force. She had a repetitive dream of being shot by different men. She became pregnant at age 15 and underwent a therapeutic abortion. This pregnancy resulted from a sexual liaison that went beyond her control; her abiding anxiety was "going out of control." When she first began working, her greater exposure to men led to increased sexual activity. She diverted most of her energy to juggling dates, and when she could no longer hide her activities from her father, she would run away with one of her boyfriends. These runaways led to police and court involvement.

Her affect was characterized by mood swings, with depression usually following sexual relations. She was overly verbal, highly energetic, slept poorly, and maintained stable weight despite eating excessively. With therapy, the patient's social behavior became moderated; she became engaged and was married at age 18.

Case 4. This small, chunky girl was first seen at age 16 when she was a senior in high school. She was the only child of professional parents and had been born after two miscarriages. Her mother had received progestational agents because of early signs of miscarriage during the first trimester of pregnancy. The girl's childhood had been marked by intellectual and sexual precocity. She entered first grade at age 5 and skipped the second grade. She was a prodigious early reader and was interested in solitary pursuits rather than peer companionship. Her mother recalled that the girl had masturbated frequently during early childhood. Onset of menses, at age 9, was uneventful.

Furtive running away and sexual intercourse began at age 12. The girl was musically talented and used music practice rooms in a conservatory for numerous rendezvous with boys. She entered a private school at age 13 and began liaisons with male teachers. She was moderately hirsute and underwent electrolysis at age 14. She was expelled from the first private school for stealing examination questions. Running away became more frequent at age 15; at that time her use of tranquilizers brought her to the attention of the court. When she was 15 she was simultaneously involved with men who were aged 22, 35, and 44. She was an avid reader of science fiction and attended conventions of science fiction buffs, where she formed more sexual liaisons. At 15 she started using oral contraceptives and also had her first homosexual relationship, finding it "interesting but not satisfying." She was expelled from a second private school for selling drugs. She kept a small pharmacy of medications for herself and was particularly concerned about having antibiotics on hand to take after sexual relations to prevent venereal disease. She ran away shortly after her mother's hospital-

ization for depression and was apprehended by police while hitchhiking.

In therapy she was restless and paced about the room. Her speech was studiedly profane. She challenged psychiatric theory and spoke of having read textbooks on abnormal psychology. During therapy she did attempt to cut down on her use of drugs. However, her hypersexuality continued, especially when nocturnal masturbation no longer helped her get to sleep.

Case 5. This 15-year-old girl, the older of two children in an intact family, was referred because of her continuing incorrigibility. Her mother's pregnancy was marked by repeated threats of miscarriage, and after bed rest and sedation, progestins were prescribed. As an infant, this girl was described as "totally active—always on the go." She had a strong masculine identification and was very jealous and demanding after her brother was born. She continued to out-run, out-swim, and overpower the brother, even when he was 14 and she 15. Menarche, at age 12, was uneventful.

She started stealing and lying at the age of 11. At 13, in the seventh grade, she began meeting older boys for sexual adventures. She began to roam farther from home, ran away, and became a burglar's accomplice.

In therapy she remained manipulative and deceptive about her sexual encounters but her stealing and conjoint burglary ventures became less frequent. She was quite muscular and prided herself on being able to "punch like a man." She was involved in several fights in bars. She enjoyed playing football, diving, and gymnastics, and rebelled against wearing clothing other than shirts and blue jeans. She was impatient with studies, usually restless in a classroom, and often took drugs to "relax." After she had terminated probation and therapy she confided that she had settled down sexually at age 18 and was living with two lovers who were brothers. "One is never enough, but I don't have to run out to find it the way I used to."

Case 6. This 14-year-old girl was the oldest of three children; she had two younger brothers. Although her parents' marriage was intact, her mother had been episodically depressed, requiring hospitalization when this patient was 9 years old. Her pregnancy and delivery were said to be uneventful. She had been a precocious child, walking at 7 months and talking in sentences at 1 year. She had a history of glomerulonephritis and had been hospitalized for 1 month and had received steroid injections at age 7. Menarche occurred at age 11 and was followed by stealing and meeting boys on the sly.

Her involvement with the juvenile court began at age 12 after she ran away many times. At age 13, using forged identity, she accompanied an 18-year-old man on a number of journeys and eventually married him. She was apprehended and brought to a detention home where a psychiatric examination was ordered. She escaped a number of times from relatively secure detention facilities.

In early psychiatric interviews she alternated between noncompliance with withdrawal and angry depression. When seen 3 years later she was extremely verbal and quick moving. She had been assaultive on occasion and made it her business to become a leader of other young female prisoners whenever she was incarcerated. She made several suicide attempts by cutting herself and taking an overdose of drugs. She was proud to be a tomboy but admitted to enormous sexual needs. Thioridazine (prescribed during two incarcerations) had blunted her sexual drive. She ran away many times for the express purpose of sexual adventure and noted "there's no high that can beat getting it on." She enjoyed sex and did not care whether she knew her partners, whether they cared for her or she for them, or whether liaisons were heterosexual or homosexual. What depressed her was confinement and the restriction of motor activity. She maintained contact with her childhood mate after the marriage was annulled but became attached to another, older man who became her primary interest. At age 18 she was single and maintained liaisons with one man and one woman. At the same time she was having sexual relations with others several times a week.

Case 7. This 17-year-old girl was seen in psychiatric consultation for the chief complaints of depression and shoplifting. Her mother had received a series of injections in midpregnancy due to the threat of miscarriage. Her family was intact; she was the youngest of three girls. She described a relatively happy early childhood during which she played as "one of the boys" and often recalled street games with boys as "carefree days." This happy period ended with precocious development and menarche at age 8.

Her classmates in grade school were "in awe" of her, and although she recalled being told about sexual matters early, she thought she was "bleeding to death" with her first menses. She was not treated for possible sexual precocity, but at age 15 she was discovered to have a benign thyroid goiter with nodules. She was treated with whole grain thyroid hormone, usually from 2 to 4 grains daily. She had been masturbating "as long as I can remember." She was intermittently enuretic from age 11 to 13. Her first sexual relations, at age 10, were with a girlfriend who slept over; this was followed by other similar encounters. At age 14 she attempted to hang herself with a blanket and was hospitalized briefly. She had repetitive dreams of being chased by monsters. Her first intercourse was at age 15 because "it was high time to get broken in." She spoke of numerous sexual encounters in a bragging fashion, with persistent cynical remarks about the inadequacies of her partners. She often would "wear out" male partners and alternated male and female lovers. She often masturbated as frequently as eight times daily. She used pseudonyms and ran away for "thrills."

Her court involvement began at age 15 after her apprehension for shoplifting. She had a pregnancy terminated by abortion at age 16 and was referred for psychiatric consultation by the court at age 17 after another series of shoplifting incidents. She regarded her hypersexual behavior as "tension relieving" and was "proud of my appetite." Her depression alternated with the more usual hypomanic energy and nonstop recounting of her many adventures. Shoplifting provided her with only another variety of thrill. She was bright and creative and managed to curb her shoplifting while on probation. When she turned 18, she left home to pursue a modeling career.

DISCUSSION

These seven girls shared several characteristics. All of them were of above-average intelligence, with an average IQ of 122. Their age at menarche was usually quite young, most of them were hirsute, four of them had low voices, and they tended toward mesomorphic build. Three of the girls had marked acne when I saw them. Their breast size was perhaps smaller than average. None of the girls had frank gynecological evidence of clitoral hypertrophy or other evidence of possible hermaphroditism. The mothers of four of the girls had received hormones during pregnancy because of the threat of miscarriage. Two of the remaining three girls had a history of excessive levels of adrenal hormones, one endogenous and one exogenous. The exposure to potentially virilizing hormones forms the common denominator of the group, with only one exception.

In 1958 Wilkins and associates (11) first described the masculinization of the female fetus associated with the ingestion of progestins during pregnancy. From 1950 to 1975 progestin therapy was commonly used in cases of threatened miscarriage and also for pregnant diabetic women. Only recently has the Food and Drug Administration (12) warned of its poor efficacy and problems with its aftereffects. Following up on a study of IQ and psychosexual identity in progestin-affected girls, Ehrhardt and Money (13) found significantly higher IQs and tomboy behavior. One of their positive findings was the girls' great interest and participation in muscular exercise and expenditure of energy. In a later study, Ehrhardt (14) found that girls with fetal masculinization had a significantly higher interest in a career and a lower interest in the traditional maternal role. These girls preferred boys' playtoys and had little interest in dolls.

A Russian study (15) of women who were treated later in life for a virilizing adrenogenital syndrome found that they had a significantly higher than average general educational level. This study, which employed anamnestic interviews, found elevated sexuality in these women, with increased libido and a high frequency of sexual dreams and masturbation. Discussing innate masculine-feminine differences, Gadpaille (16) described girls who were reared as females and exposed to the cultural stereotypes of femininity but were still masculine in their preferences. Conversely, Yalom and associates (17) have shown that prenatal exposure to an estrogen-progesterone combination has a demonstrable effect on the masculinity of boys and has been shown to reduce expected levels of aggression, assertiveness, and athletic ability.

When we turn toward a summary of the behavior of the seven girls whose delinquency was associated with hypersexuality, we note that there was a high incidence of running away and serious suicide attempts. Several of the girls were quite aggressive and assaultive, and stealing was a common antisocial activity. Clinically, all of the girls had definite signs of hypomanic ideation. High energy levels, rapid and overinclusive speech, and labile mood swings were characteristic of the group. None of the girls was frankly psychotic.

It is not possible to conclude from this small group which cultural, psychodynamic, and biological factors are critical. It is postulated that girls who have been exposed to virilizing hormones in utero or later in childhood can be characterized by hypersexuality, hypomania, high intelligence, and aggressiveness. Some of the delinquent manifestations of these girls and young women are seen as extensions of their "psychovirilization." These girls were therefore delinquent by default and as a consequence of their hypersexuality.

Psychotherapy combined with legal probation had some effect on the delinquent behavior but was less effective in reducing hypersexual activity. Physicians should be on the alert for young men and women born in the 1950s and 1960s who may have been exposed to feminizing or virilizing agents. Perhaps in the future some of the clinical problems of these at-risk patients who come to the psychiatrist's attention can be ameliorated by hormonal therapy, combined with the psychotherapist's appreciation of the role of these neuroendocrinological factors in certain behavioral manifestations. Hypersexuality may then be conceived of in terms of a biological drive that may have been primed by exposure to virilizing agents and is expressed in the force field of psychodynamic considerations. The association of hypersexuality with delinquency in these adolescent girls is thought to represent a defect of behavior engendered by the biological priming.

A General Systems Approach to Severe Family Pathology

BY STEPHEN FLECK, M.D.

The author proposes a general systems approach to the examination and understanding of family functioning. Scrutinizing the family as an open system with 1) evolutionary goals and tangible tasks, 2) a need for "semipermeable" boundaries, 3) cultural and subcultural communication modes, 4) leadership effectiveness, and 5) the nature and age-appropriateness of the affective bonds will enable clinical judgments about family functioning that indicate general system competencies and defects. Such a framework may also lead to a typology of family process because the major functions of the family as a system (creation, nurturance, enculturation, and guidance of the young into adulthood) can be evaluated regardless of symptoms or diagnoses.

TOLSTOY'S *Anna Karenina* begins with the statement that all happy families are similar and that all unhappy families are unhappy in their own fashion (1). A general systems approach to family study and assessment may help, not to disprove Tolstoy (because family clinicians must agree with him) but to bring some measure of order into the chaotic world of family pathology. The clinical participant-observer needs a superordinate framework and referential system to categorize and order his observations of family behavior. Like other systems the family can be examined and evaluated on five criteria: 1) its central functions and goals, 2) its leadership, 3) the regulation of the boundaries among system components and between the group and the outside, 4) managerial links and affective bondages, and 5) the effectiveness and relevancy of communication inside the system and between it and the outside world (2–4).

These five system constituents and forces are distinguishable in any functioning complex but are also interdependent, and malfunction of one sector affects all others. For instance, leadership declines if there is communication disturbance, and boundary diffusion and affective imbalances can interfere with task pursuit. It is the circularity of these attributes and forces that must be appreciated, as well as the cumulative effects of dysfunction or deficiencies. One defect passed on along an assembly line may render the end product unworkable, and developmental failure at a particular stage in the human organism can interfere with the emergence of an internally and socially integrated adult (5).

Biosocial and cultural givens require that the family humanize the young by teaching them not only about themselves and how to live within the family but also about the mores and cultural values of the society. In addition to these evolutionary goals of the family as the keystone of society and the aforementioned system functions, this group must also accomplish tangible and specific tasks related to self-sustenance.

The evolutionary tasks are as follows: effecting a marital coalition capable of forming a triad of parents and infant, nurturing and weaning the infant to enable it to exist as a body apart from the mother, and imparting language and intrafamilial behavior modes epito-

Revised version of a paper presented at the annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Fleck is Professor of Psychiatry and Public Health, Department of Psychiatry, Yale University School of Medicine, 25 Park St., New Haven, Conn. 06519.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editor considers this material to constitute a comprehensive analysis of the topic.

mized by the resolution of the oedipal phase. Furthermore the family must introduce the child into society in school and through peer relationships, which provides familiarization with society's tools and values. Tools include formal learning, communication mastery, and competence in abstract and symbolic thinking and expression. After puberty the child turns again more toward relationship issues, establishing not only his/her sexual identity but also undertaking more lasting and intimate relationships with peers. The family system is involved in all these stages; malfunction may burden and handicap offspring severely, particularly in the process of emancipation from the family to become a full-fledged adult member of society (5–7).

As a system, however, the family is more than an evolutionary production line. Parents must not only function as gender typical adults in their society but also tend to the other system parameters. Boundaries must be managed so that within the group each member is afforded a sense of "I" as well as "we." Boundary is a difficult concept but is essential for a sense of integrity for the individual and the family. Boundary has two dimensions, time and space, each with tangible and intangible aspects. For instance, boundary management between the family and its community must be appropriate to subcultural norms (e.g., when a child enters school). Later, the child must cross the boundary comfortably for other purposes and for longer periods without losing the sense of family belonging, which must persist through life lest a person lose contact with his past. Another crucial boundary within the family is generational, distinguishing the parents as leaders and teachers and the children as followers and learners.

Affect flow in the family is another basic function, also determined by the parents' behavior and leadership. In brief, the maintenance over time of a positive balance of good feelings and mutual fondness is essential. The initial physical closeness between parents and child must be reduced so that a more abstract deeroticized sense of closeness evolves, with sexual intimacy limited to the parents. The resolution of conflicts and the modulation of feeling intensity through example are the leaders' tasks in maintaining a harmonious and functioning group (6).

Communication distinguishes human behavior from all other. Animals exchange signals and can even recognize feeling states in another being (8), but only humans can make feelings explicit, learn the history of their species, and mentally project future action through language-derived symbols and abstract ideation before implementing it. Linguistic competence in the family consonant with communication styles of the society is therefore as crucial to the evolvement of individual integrity as it is to effective social participation (9–11). Observing familial communication, therefore, is also a major examination tool of family functioning, just as dyadic interviews and participant observation constitute the psychotherapist's matrix for evaluating intrapersonal processes.

CLINICAL ILLUSTRATIONS

The following is an opening vignette from a meeting of a family and two hospital staff members:

Mother: It's nice to have such lovely weather. [It is pouring outside the window.]
Daughter: I am Nikita Khrushchev.
Father: [Shakes head mildly and lights a cigarette.]
Therapist: Daughter seems to be responding to mother's nonfactual statement.
Mother: It is raining, but how are you, doctor? You look well.
Father: We had a good visit.
Daughter: Can I have a cigarette?
Therapist: A good visit?
Father: Yes, of course we didn't go out but I had some good talks with daughter.
Therapist: Yes?
Daughter: [Leaves room.]

One need hardly be a skilled observer or student of family process to conclude that this is indeed a very disturbed group of people, leaving one guessing as to who might be the patient. It is also not difficult to draw inferences about the individual malfunctionings exhibited, through the use of the referential systems of psychoanalysis and psychodynamics. General systems principles also seem useful to categorize the behavior and dynamics of this unhappy group.

One can say that in one sense no communication was taking place—these people did not even greet each other and no one validated anyone else's statement or behavior. The comment about the weather is a classic opening gambit for strangers seeking to begin an agreeable discourse. In this vignette it was also an idiosyncratic distancing gambit; it sought no agreement because it contradicted the obvious. However, it was not lost as a stimulus, eliciting a crazy response from the daughter and a kind of nonverbal "let's ignore it" from the father. The father's first statement was equally inconsistent with his own attitudes and wishes. Another conventional gambit, "We had a good visit," is nice to say if one wants to elicit agreement, but it was nonfactual; indeed, the good visit he had wanted, even demanded, was that his daughter should be allowed to be with the family away from the hospital. His wish was not granted, and everyone in the room knew this.

Thus communication in this group was earmarked by misstatements about observable or known facts and mutual nonvalidation arousing a high level of anxiety and anger in the participants. After the daughter's departure, communication between the parents continued in a challenging and disagreeable manner, and neither seemed attentive to the other's intent or discomfort (11, 12). Communication could also be categorized as fragmenting with regard not only to meaning but to the individuals involved. This gave the family therapists at least an opportunity to try to reduce fragmentation, which in this instance did not suc-

ceed. But we can agree with Wynne and Singer (12) that this type and style of communicating is indeed damaging to and pathognomonic of at least one schizophrenic member in the family.

Family behavior can also be assessed in the framework of task performance—by immediate tasks in a therapy session and by examining longitudinally the general and basic evolutionary family task performance. In this instance the family had been informed in previous sessions that the task was to converse with each other, to improve contact with each other, and to understand their difficulties better. Task performance in the vignette was nil if not negativistic, arousing the observer's suspicion that the broader spectrum of evolutionary task achievements may have been equally deficient if not destructive. Indeed, the family history revealed that there was not one phase during which this triad functioned adequately or in a manner appropriate to the daughter's age and developmental needs.

The mother suffered recurrent illnesses requiring lengthy hospitalizations almost from the time of her daughter's birth; an effective mother-daughter relationship never developed because, even when physically present, the mother was rarely emotionally available to her daughter. There was no consistent mother substitute, this role having been filled by a succession of maids, two older sisters, and the father to a considerable extent. Yet it was not a typical single-parent family. The maternal behavior on the part of the father interfered with the emergence of any real oedipal situation, let alone any resolution, and this particular father's maternal attention to the daughter extended through puberty. During this period there was no real family unit, in part because of the wide age spread among the children but also because of the mother's recurrent but unacknowledged difficulties.

At about puberty the daughter began to show psychotic symptoms and behavior and became the identified patient for the next 6 or 7 years. On the other hand, the family had not identified the mother as a psychiatric patient and still referred to her illnesses as infections in spite of her having been on antipsychotic medications for years. In terms of evolutionary family tasks, the psychotic daughter never approached any emancipation phase and faltered in early adolescence, thus requiring psychiatric hospitalization. She has claimed to function on an age level of 4.

One can discern the extreme degree of failure in every phase of system goals, representing almost in caricature our formulation, advanced some 12 years ago, of schizophrenia as a deficiency disease of family functioning and task performance (6, 9, 13).

In this chaotic family, boundary management was equally pathological. In the session, the family members exhibited rigidly drawn noncontiguous boundaries, each withdrawn from the others in his idiosyncratic stance. However, we observed also extreme intrusiveness, a violation of ego and intergenerational boundaries in the form of inappropriate physical contact between father and daughter. She has also perceived her mother as being sexually interested in her.

Children are usually expected to negotiate family boundaries without undue discomfort when entering school, which presupposes some degree of separation mastery within the family. The children in this family were tutored at home because of the father's fear of his children suffering contamination and infections in school. Boundaries were overcontrolled and rigid instead of being permeable and transgressible in line with children's age-appropriate needs. The isolation of the identified patient almost from birth illustrates further boundary mismanagement, punctured by inconsistent intrusions almost literally into her body space.

The parental role reversal was blatant, and obvious role model defects in both parents constituted leadership failure evident even in this brief vignette. Considering this family from the standpoint of system integrity, we see a system that mismanages boundaries, is not led properly, and in which affective bondages and interactions (communication in particular) interfere with self-definition and task performance. Such a system can neither function nor achieve goals, whether these are givens or explicitly defined as in the family meeting.

A brief description of contact (or noncontact) with the family of another hospitalized patient may illustrate further boundary mismanagement and other system defects. According to the social worker's record, "This family met on common ground in their wish not to be involved with the hospital or in treatment. Family meetings were difficult for all of them, particularly for the mother and the son (the identified patient). They collaborated in trying to keep discussions as irrelevant as possible and had a variety of maneuvers to avoid engaging themselves. The father used a style of legal interrogation with his son and was apt to get into lengthy debates about the details of an event. He also claimed total ignorance of anything having to do with emotions, interpersonal relations, or treatment. He became quite irritated with his wife when she occasionally revealed that he had been angry with his son, with the social worker, or with the way a family meeting had gone, but usually denied having said any such thing."

The mother's tactics included attempts to discuss the social worker's personal life, other patients, current events, and psychological theories. When the session became more personal, she tried to force her son to confess that he had a happy childhood; she was quite angry at the hospital staff for stimulating him to think about his life and his feelings. As she became more disturbed and vulnerable, her intense conflict between her feelings of hostility and rejection toward the patient and her enormous guilt about these feelings were increasingly apparent.

The identified patient was the second child and only son in a family of four and was clearly not wanted by the mother. Her then 3-year-old daughter already was in a day nursery when the second pregnancy occurred.

She had at this point turned her interest and energy toward various community activities and was also very much involved with another man. Shortly after being sent to nursery school at age 3, the son developed poliomyelitis, from which he eventually recovered completely. Because his prolonged illness had produced regression and developmental stagnation, he was not even ready for nursery school by the time he was 4; his mother, however, ignored such messages from teachers and insisted on continuing with the out-of-home program so that she could pursue and nurture her community interests and ties, which interfered with the family's needs at the time and with family life. In this instance, boundary management failed because it was not congruent with this child's emotional needs or with engendering a sense of family unity and bondage.

Movements of the young across the family boundaries are predicated on separation mastery and on the child's inner certainty that a person out of sight is not lost ("object constancy"), neither of which can occur in the context of pretense or sham, which characterized the parents' affective and communicative behavior with each other and with their children. The son's psychosocial immaturity, evidenced by separation difficulties, was ignored.

This boundary mismanagement is different from that of the first example. In both families, contact is avoided so that there is little affect flow, and everyone remains encapsulated. However, in the first family distance alternates with intrusive excursion into each other's affective space, and encapsulation, even autism, is achieved through symbolic distortion and idiosyncratic, nonvalidating communication (7, 12). In the second family, communication sounds and seems rational but is not truthful or expressive. Feelings are avoided and denied but not distorted, projected, and/or fantasized. The second family spawned a psychopath, the identified patient, who became a master in the family's instrumental, manipulative, and nonexpressive communication style. "Manipulative communication" means that the speaker focuses on whatever reaction he wants to elicit in the listener, whether the intent is pleasing, duping, or angering the other.

In this family, with a very disturbed, intermittently depressed, but mostly sociopathic patient, more than one essential systems paradigm was violated. Boundaries were mismanaged intrafamilially by imposing emotional distance and extrafamilially through pushing the younger members beyond the family sphere before adequate individuation and separation mastery had been achieved. The generation boundary, although too wide, was not violated; however, nurturant tasks were accomplished marginally at best. Goal pursuit in general was inadequate and deceitful, both in the therapy setting and in the life of the family; for instance, no attention was paid to the patient's misconduct and deceitfulness unless evidence was furnished from outside by schools or police.

Finally, emancipation was never joined as an issue at the usual age because of the antecedent evolutionary task failures in mastering separation, although the patient was physically out of the home in various boarding schools from early adolescence. Yet his misbehavior, leading to repeated expulsions, was never acknowledged as such, let alone as a veiled message of his unpreparedness to live without parental care.

There was a good deal of verbal emphasis on love, but both the record and the session behavior were replete with indications of mutual rejection and hostility between the spouses and between mother and son. Communication in sessions was often disputatious, especially when unacceptable affects had to be denied. Whereas interparental communication was superficial, rational, and seemingly logical, it was neither affective nor truly responsive, and the patient often talked in fragmentary fashion like a child unready to think in sentences. Communication was substantively deficient in that it lacked expressiveness, and affective exchange was not taught or practiced; instead, communication was manipulative. Leadership was perfunctory and stereotypic but not grossly aberrant. It was deceitful because of the emphasis on appearances; i.e., whatever looks all right is all right. Thus we find communication and leadership marginally acceptable but affective forces, boundary regulation, and some family tasks grossly deficient.

DISCUSSION

I have attempted to demonstrate briefly one method of how to order initially confusing, disturbed, and disturbing family behaviors. These two examples derive from very aberrant families, each with at least one member in need of psychiatric hospitalization.

The information obtained both from direct participant observation and from historical exploration can be ordered by examining the basic characteristics of any general system—task and goal pursuits, leadership, boundary regulation, affective bondages, and effective communication. Since the central mission of the modern nuclear family is the nurturance, enculturation, and guidance of the younger generation into adulthood, the history must be relied on for the most part to provide relevant data (6, 9, 13, 14). However, leadership, communication, boundary management, and the affective bonds are also observable and available for inferences from behavior in family meetings (7, 11, 15). These procedures have only been indicated here and should be described in greater detail in the future.

It can be pointed out that this approach may serve not only to conceptualize family functioning and malfunctioning along two axes, historical and cross-sectional, but also to establish a family typology, specifying normal and abnormal system functioning and performance according to the aforementioned principal system paradigms.

Families as severely disturbed as those I have described demonstrate multiple (and in one instance

global) system deficiencies; many more families have system deficiencies that are more discrete and do not affect all parameters of system integrity and all evolutionary stages of family task performances (7, 12, 16).

As far as schizophrenia is concerned, this illustration and like considerations confirm our earlier thesis of pervasive family system deficiencies in the background of young schizophrenic patients (13). In the first example the parents were severely disturbed, rendering the formation of an effective parental coalition and leadership impossible. The parent-patient triad seems deficient in all evolutionary phases, and there are boundary violations of personal space and defects in family-community relationships. Emotional bonds are inconsistent, probably incestuous in quality, and anxiety laden. Communication was ineffective in both families—bizarre, fragmented, and fragmenting to the speakers in the first and amorphous and dissimulating in the second (12, 13, 16).

The second family as a system was different from the first. Although both parents could be considered neurotic (the mother suffered various psychosomatic symptoms, the father showed obsessive-compulsive traits), neither was grossly disturbed, and they effected a workable albeit superficial marital coalition. However, the coalition did not extend to the parental tasks, and leadership and affective assertions in the family were a sham. Crises and family failures were denied instead of coped with, and boundaries were kept noncontiguous within the group and were almost nonexistent between the family and the outside. Communication was earmarked by its exclusively instrumental usage (an emphasis on its sounding right whether or not it was true and meaningful). The sham behavior extended to the family's task performances—there was nurturance without warmth, enculturation without substance (the principle that as long as behavior looks all right, it is all right). There was no family togetherness in leisure or crisis, and emancipation was also a sham in that the patient's signals of his inability to cope with separations were ignored.

CONCLUSIONS

The general systems approach of defining a family typology seems useful in ordering family behavior data and may also correlate with certain of the major clinical entities, a prospect reinforced by other family records so analyzed. This correlation may be more quantitative or cumulative than qualitative. The data so far suggest that the number and severity of systems defects may distinguish pathological outcomes rather than any particular intrinsic defect.

In summary, scrutinizing families as an open system allows us to arrive at sequential judgments and categorizations that differ from such simple polarities as normal versus abnormal or healthy versus pathogenic. General systems theory permits cross-sectional and longitudinal examination of the group not only in terms of the special group that is the family but also as it pertains to any collective of interacting forces. Judgments about the system's behavior and past performance in terms of the family's role as the keystone of society can then be made independent of presenting disturbances, symptoms, or traditional clinical classifications.

The Fatal Myth of Death in the Family

BY E. MANSELL PATTISON, M.D.

The author hypothesizes that the observed pathogenic effects on a child of the death of a parent are the result of the family's culture-bound inability to integrate death as a natural part of the process of living. The family tries to deal with death by the avoidance mechanisms of myth and family mystification; it is this process which is pathogenic rather than the experience with death itself. To illustrate his thesis he presents the case history of a man who was fatally affected by the family myth and mystification process.

THIS PAPER EXPLORES the function of the family as a psychosocial system in the management of experiences with death. In particular, I shall examine how the family system copes with the death of a parent.

Psychiatric opinion is divided on the questions of how traumatic the death of a parent is to a child, how irreversible the effects of such a loss are, and how these effects may be meliorated for the child. At the pessimistic pole there are those who view the death of a parent as a major irreversible trauma. Moriarty (1), for example, stated, "Those who suffer from exposure to death in early childhood may be haunted for the rest of their lives by these memories" (p. 120).

A more mediating position holds that experiences with death are a severe childhood stress but not necessarily a dire trauma. For example, Laufer (2) stated, "While itself not pathogenic, object loss can become the nucleus around which earlier conflicts and the latent pathogenic elements are organized" (p. 290). Similarly, Furman (3) stated,

> When a child's parent dies, each surviving member of the family faces so complex and difficult a situation that no form of assistance may seem adequate to the task. Yet, many children and parents . . . can master the stress. (p. 296)

Finally, the nonpathological view holds that death has become pathogenic because sociocultural taboos prevent child and family from appropriately coping with death (4). In Victorian times cultural denials and taboos centered on sexuality; therefore, sexual experience generated psychopathology. Today cultural denial and taboos that center on death result in death's generating psychopathology (5).

The following constitute the basic theses of my paper: 1) much of the observed psychopathology of experiences with death during childhood results from a sociocultural failure to appropriately integrate death as part of natural life experience; 2) the family system incorporates and embodies this cultural denial of death; 3) the family management of death is dysfunctional for both the family and the child because it fails to appropriately integrate death within the family; 4) the family deals with death through the avoidance mechanisms of family myth and family mystification; and 5) the family myth and mystification processes are the pathogenic elements in the death of a family member rather than the death per se.

CASE STUDY

Harry, a 40-year-old physician, came for psychotherapy with the chief complaint of alcoholism that had started four years earlier after the sudden death of his wife Florence. She had had undiagnosed leukemia that erupted in fulminating symptoms and sudden death following four days of illness. Harry expressed profound and unrelenting guilt for her death, which he tried to drown in alcohol. He stated that his marriage to Florence had been idyllic: she had been the perfect woman for him as well as acclaimed as the epitome of femininity and motherhood by all who knew her.

After three months of therapy, Harry's intense guilt was relieved, his reactive depression was resolved, and his drinking was controlled. He was able to return to his medical practice and function at a socially competent level. An intelligent, articulate, psychologically sophisticated, and introspective man, he recognized that his neurotic grief reaction and alcoholism were the symptoms of long-standing life conflicts. The next period of psychotherapy revealed Harry's history.

Harry was an orphan who had no knowledge of his biological parents because he had been left on the doorstep of two unmarried sisters as an infant. These two women, Aunt Millie and Aunt Mary, reared him to adolescence. Harry perceived the younger sister, Aunt Millie, as kind, sweet, and gentle; he lived with her until he started kindergarten. Then, for reasons unclear to him then and when I knew him, he had been moved to live with the older sister, Aunt Mary, whom he perceived as stern, severe, and businesslike. He mourned his separation from Aunt Millie, who had been like a mother to him. Although he saw Aunt Millie on holidays, he was nev-

er again allowed to live with her. During therapy, Harry expressed affection for both women, and his visits with them several times a year constituted family reunions for him.

Aunt Millie had had a boyfriend for many years, Mr. Brown. Mr. Brown had always taken a kind, fatherly interest in Harry and had even provided some financial support for him. Harry was told that Aunt Millie and Mr. Brown planned to get married after the death of Mr. Brown's sickly wife and that they would then legally adopt him; Harry would then inherit Mr. Brown's business. However, when Harry was 14 Mr. Brown rather than his sickly wife died. After that it seemed to Harry that he was even less welcome in Aunt Mary's home. He felt dejected, rejected, and alone, so he ran away. He lived in a series of friends' homes until he could work full-time and live alone. An able student with a winsome personality, he worked his way through college and medical school with the help of scholarships. He met his wife Florence in college, she helped him through medical school, they had three children, and he embarked on a medical career that was successful for 10 years—until the sudden death of Florence.

At this point it became clear that Harry had not developed his severe guilt, depression, and alcoholism immediately after the death of Florence. After an initial period of mourning he seemed to have made a good adjustment. Within six months he married his second wife, Sarah. It was after this second marriage that his disturbing emotions and symptoms began to develop. Because the second marriage was happy, mutually rewarding, and successful, Harry could not account for his increasing inability to function.

Sarah had been Florence's roommate in college. The two women presented contrasting personalities. Florence was kind, sweet, gentle, and unassuming, a contented and loving wife and mother. Sarah, who had never married, was rather brusque, businesslike, and capable. She had pursued a successful career as a psychiatric social worker and had continued to remain friends with Florence and Harry during the years. As a matter of fact, Harry and Sarah had had intermittent sexual liaisons during the 15 years of his first marriage. Neither considered this a threat to his or her relationship with Florence, who ostensibly was unaware of the liaisons. After Florence's death Sarah immediately volunteered to help with the children; shortly thereafter she and Harry were married.

During this period in therapy Harry continued to function well in his medical practice, his social life, and his marriage; he also remained abstinent from alcohol. However, as the history of his life unfolded, he began to experience new and disturbing affects. He reported a sense of foreboding, as if his existence were to be snuffed out, and an inchoate stirring in his stomach, as if his insides were being wrenched. Then he told of a sense of panic and dark anxiety, as if he must jump and run. He was unable to locate himself and felt bewilderment, confusion, and diffuse ennui. This amorphous state of profound panic was more than he could endure. When he remembered that he had felt this way when he left Aunt Millie he shuddered. He felt this way when Mr. Brown died. He felt this way after his first marriage. He felt this way when Florence died. However, he had endured all of these crises.

The only times he felt he could endure now—the only times when he could emerge from this engulfing lostness—was when he talked to me; there did not seem to be anyone else who could really be with him. He felt that his wives were an attempt to create a mother, but they were not his mother. His aunts were an attempt to create a mother, but they were not his mother.

"Where, oh where is my mother?" he sobbed. "If my mother is dead then let her be dead. But maybe she is alive. Sometimes I think Aunt Millie is my mother, and I think Mr. Brown was my dad. I know it's not true, but I wish it were so. It wouldn't have to make any difference to them. But just to know that I came from somewhere, that I belong to somebody, that I'm not just a nothing. God! How can I be? I'm nothing, nothing, nothing. Mother, mother, mother, where are you? Dead? All right. Give me your grave. Let me put flowers on it. But be, damn it, be! You know, sometimes I know Millie is my mother. I don't want anything from her. I just want to know. I have to have a mother! God, oh God, have mercy on me!"

The next day Harry went to see Aunt Millie and Aunt Mary. He was armed with the resolute conviction that they held some knowledge of his parentage. He returned crestfallen to report that there was nothing to report. Aunt Millie and Aunt Mary said they knew nothing about his origins and that he was certainly not the son of Millie and Mr. Brown.

At 2:00 a.m. the next morning Sarah called me: Harry was dead.

Harry's epitaph is not a night of whiskey drinking that failed to drown out his senses and then the need for a few barbiturates to bring on sleep. Nor is it the will that Harry left: he requested that his ashes be strewn over the sea. Rather, it is a prosaic bit of historical fact. Two weeks after Harry's death, Sarah went to visit Aunt Millie and Aunt Mary to offer her condolences. Shaken by Harry's death, they said they could finally say what could not be said while he was alive. Aunt Millie was his mother, and Mr. Brown was his father. To protect Millie's family as well as Mr. Brown's, Millie, Mary, and Mr. Brown had made a pact that Harry should never be told. When Millie and Mr. Brown had resumed their relationship they had protected themselves from Harry by shipping him off to Aunt Mary.

Harry was right all along. He knew he could not know what was known.

THE PSYCHODYNAMICS OF DEATH IN THE FAMILY

The story of Harry is the story of his several families. To begin with, Harry was never provided an unambiguous mother object. He was first reared by two sisters, neither of whom assumed primary responsibility. Although he lived with Millie, she did not claim him as her own child, as a foster child, or as an adopted child. The basic ambivalence of the infant toward the mother was reinforced by this ambiguous status. The splitting of the mother object into "good mother" and "bad mother" was reinforced by the presence of two mother objects, one of whom assumed a good, accepting role while the other assumed a bad, rejecting role. Harry was given no opportunity to resolve his ambivalence and to attain a constant mother object. He had no basic nurturant mother object to internalize and use to build his constant object self.

A second step in object identification was also blocked. Harry was offered a tentative identification with Mr. Brown. However, when Mr. Brown reentered the scene Harry was just at the onset of the oedipal stage. The desexualized good mother object, Aunt Millie, was transformed into a sexualized wife with

Mr. Brown. Harry was not offered identification with Mr. Brown or allowed to retain a desexualized relationship with his good mother. Rather, he was sent away to his bad mother, Aunt Mary. He was not told why. Bad mother was better than no mother at all at this point, and Harry was still given the hope of adoption by Mr. Brown and the inheritance of his business. The opportunity for identification with Mr. Brown made life with bad mother tolerable, but Mr. Brown died, and with that death the tentative identification with a father was lost. Harry could no longer tolerate life with bad mother, so his only alternative was to run away.

As Harry reached adulthood he recapitulated his search for a mother. He married a desexualized good mother object, but the sexual bad mother was present from the beginning of the courtship and throughout the first marriage. Eventually, he was left with the bad mother. Just as the two aunts had colluded in their mother role, so the two roommates seem to have colluded in the wife role. The death of the first wife evoked bewilderment and guilt, just as the loss of the first mother had evoked bewilderment. Florence's sudden and mysterious leukemia was like the unexplained loss of Aunt Millie.

It is noteworthy that Harry's depressive and alcoholic symptoms emerged only after he married Sarah. In this case, Harry again found temporary hope in identification with a male father object—the psychotherapist. The threat from the bad mother (his second wife) was attenuated, and Harry was able to attain symptom relief. The psychodynamic analysis in therapy uncovered the projections into his current life, thus releasing his wives and myself at least partially from the transference roles. On the other hand, this placed Harry right back at the earliest stage of object relations: the search for a mother object and a profound primordial panic. He could not be a person without a mother object on which to ground his sense of self. A dead mother would release him from the search and allow him to recathect living objects, a rejecting mother would give him a reality to work with, but the third alternative was unbearable—a mother who gave cues recognizable in preconscious form that declared he was her son and verbal cues that declared he was not.

The family myth declared that he had no known parent, but the mystification of the myth subtly implied that the myth was myth. Psychotherapy dispelled the clouds of mystification. Harry attacked the myth. When it was thrown back into his face, he knew he had lost: he could not have the truth about himself. If your mother does not acknowledge your existence, how then do you exist? Harry could not.[1]

[1]I acknowledge that this cursory case summary may appear to provide too pat an analysis of the object identifications, transferences, and dynamics in the interest of stressing formulations pertinent to the theses of this paper. I am also aware that continued exploration in psychotherapy may have stirred up previously repressed material leading to Harry's suicide. Mea culpa. Becker (6) touched on this dilemma for all therapists: he said we should have a sign on our door that says, "Danger, real probability of the awakening of terror and dread, from which there is no turning back" (p. 271).

OBJECT CONSTANCY AND LOSS

The family matrix provides the basic critical objects for the infant. The young child must have constant objects to accept, love, and nurture him. This matrix of constant love objects provides the young child with a sense of identity (7, 8).

A major task of the family is to provide the young child with constant objects of nurturance. The loss of a parent object can be tolerated only if the family provides unambiguous definitions of the loss as well as unambiguous object replacements. (In the case of Harry there was both ambiguous definition of the loss and ambiguous replacement of the parental object.)

Schoenberg and associates (9) pointed out that loss per se is not the psychological issue but the effectiveness of the process of working through the grief. Failure to deal with psychological separations and losses in the family may lead to subsequent family pathology (10). Paul (11), for example, found family pathology not only in loss by death but in the failure to deal with the loss of the primary parent object. When children fail to resolve their symbiotic dependence on the family matrix of objects and then fail to work through the grief of loss of the symbiotic dependence, they fail to achieve mature individuation.

The process of maturation requires a movement from object constancy provided by a loving, accepting parent object to object constancy based on the internalized parent object and transformed into the self. This is necessary in order to love oneself and maintain one's own object constancy and can occur only through the gradual severance of the symbiotic object relationship; the parent must reject the dependence of the child (8).

The child learns to love himself because of rejection by the symbiotic parent object. The child must suffer this loss to recathect himself. It seems to me that the family management of parental loss is critical to the family nurturance of both self-individuation and the management of the physical loss of death. Thus the family management of death is grounded in the family management of object separation and object loss.

We may consider object separation and loss as necessary growth and individuation experiences. Heretofore we have considered object loss as an undesirable stress, whereas it may be a necessary precursor to the development of a self object. Hofling and Joy (12) reported favorable growth consequences of loss.

My first reinterpretation of death is, therefore, that object separation and object loss are necessary growth experiences that provide the anlage for later successful management of experiences with death. This thesis is consonant with the theoretical work on object splitting by Fairbairn (13). The exciting-frustrating symbiotic object can be split by the child into good object and bad object. When the child is unable to reconcile this ambivalence, he may retain the good-bad internal object split. Indeed, people may exist in reality as counterparts of the internal dichotomy, and a person may

continue to make active unconscious attempts to force and change close relationships to fit the internal role models.

If the child does not resolve the basic object ambivalance and achieve separation and autonomy apart from the symbiotic object parent, he may continue into adulthood striving to prevent the loss of the ambivalent symbiotic object. Framo (7) summarized the dynamic involved here nicely:

> Projective transferences, externalization, vindictive fantasies, vicarious participations, all serve the function of recapturing the symbolically retained old love objects who have their representation in current real family members, thus delaying the pain of loss and mourning. Object possession . . . helps prevent individuation which can result in the catastrophe of separation, the old dread of abandonment, and facing of the fact that one has irretrievably lost one's mother or father. (p. 135)

Thus observations based on ego object theory support the contention that loss of the parent is necessary to individuation and that physical death of the parent may well be considered a variant in the normal process of loss of the parent that every family must work through.

I suggest a second reinterpretation: the concept that the physical death of a parent is a pathological trauma is a myth that precludes awareness of the necessary and inevitable loss of the infantile symbiotic parent object. (In the case of Harry, there was no opportunity to work through the ambivalent symbiotic relationship with his two wives. Harry could not grieve the loss of the mother object because there was no defined object to lose. He could not achieve individuation because he did not have a concrete mother object to internalize and then separate from.)

THE ROLE OF MYTH AND MYSTIFICATION

It is clear from family therapy experience that family psychopathology often centers around family myths (14–17). Ferreira (18) defined the family myth as

> a series of well-integrated beliefs, myth-like, which members of a family entertain about each other and their relationship. . . . *The family myth is to the family what the defense is to the individual. . . . The family myth is a group defense against disturbances of changes in the relationship*. (p. 187)

The family myth is a neurotic mechanism for family coping and homeostasis in the face of unresolvable conflict. The process of mystification is the secondary mechanism that maintains the myth. Mystification, as Laing (19) explained it,

> is to befuddle, cloud, obscure, mask whatever is going on, whether this be experience, action, or process. . . . The state of mystification . . . is . . . a feeling of being muddled or confused. (p. 344)

Mystification was described by Wynne and associates (20) as "pseudomutuality" and by Searles (21) as a mode of "driving the other person crazy" by techniques that tend to "undermine the other person's confidence in his own emotional reactions and his own sense of reality."

Elsewhere (4) I have documented the evidence that our culture has developed enormous myths about death and that as a culture we engage in massive mystification mechanisms about our myths of death. I have selected the case of Harry to present because it so clearly demonstrates the process of family myth and family mystification in regard to the death of a parent. It was the myth and mystification of his mother's existence or death that drove Harry to his death. Therefore, my third reinterpretation is that the death of a family member is not pathogenic; myth and mystification of death are pathogenic.

THE FAMILY AS MEDIATOR OF MYTHS

The family is the bridge and mediator between the social matrix and the individual. It is through the medium of the family that the child learns to participate in the larger society's perceptions and constructions of reality (22). We live in a social matrix that defines death as unnatural, pathological, and even pornographic. Our society has elaborated myths and mystifications about death; it is therefore not unexpected that families transmit and participate in these myths and mystifications of death in the family (23). It should not be surprising that clinical data reveal that children as well as adults have difficulty coping with death. My fourth reinterpretation, therefore, is that children can cope with death but will have difficulty coping with family myths and mystifications of death.

Two conceptual distinctions must be noted here. I am not suggesting that the death of a parent is not stressful. The distinction is that successful family coping may enable the child to cope with stress so that it is not converted into trauma. The other distinction is between levels of anxiety about death. The first level is the experiential relationship with an object. We might term this "psychological death anxiety." The second level is the relationship of the self with the world. We might term this "existential death anxiety." Ernest Becker (6) brilliantly showed that we confuse these two levels. He suggested that only when we come to grips with the existential dilemma of death do we equip ourselves to deal with psychological loss. I concur with Becker and suggest that mystification of psychological loss is a maneuver to deal with the existential dilemma of death.

Our existential view of death is also our view of life. If we cannot admit that death is part of life, it may be that we cannot face the fundamental psychological issues of separation and individuation that contain the kernels of loss. Therefore, I suggest that the management of death in the family is rooted in the basic man-

agement of object relation separation and loss in the family, which in turn is a reflection of the existential death position of the family.

Perhaps a personal vignette can best summarize this last point. When our children were young we discussed the death of an elderly neighbor one night at supper. After some speculative questions about death, the kids got right to the gut of it. They asked, "Mom, Dad, are you going to die?" Our answer was something like this:

"Yes, we will. We are in good health and do not expect to die while you are young and need our help. You can do some things for yourself now, and when you grow older you will not need us to help you. Even if we die when we are old, we will miss each other. It will be sad, but it will be all right because you will be able to take care of yourselves. And if we happen to die while you are growing up, we have made arrangements with Aunt and Uncle for them to become your parents in our place. They cannot replace us, but they can help you as we would want to help you. We would be sorry to die now and not be here to help you and enjoy you. But you will always have our love and that is the most important thing. And because we love you, we have made plans with Aunt and Uncle, who love you too. We cannot predict or prevent our death. We will die someday in your lives. But we can enjoy our family now. And when we die you will have these good days to remember and always be a part of your lives."

A New Concept and Finding in Morbid Jealousy

BY JOHN P. DOCHERTY, M.D., AND JEAN ELLIS, R.N.

The authors describe an unexpected coincidental finding in three couples who sought therapy because the husband was pathologically jealous. In the course of treatment they found that during early adolescence each of these men had witnessed his mother engaged in extramarital sexual activity. The authors discuss the implications of this finding for further understanding of the etiology of the syndrome of pathological jealousy, its transactional dimensions, and possible psychotherapeutic approaches. They also present a typology of morbid jealousy that consists of excessive, obsessional-delusional, and ego dysfunctional forms.

PATHOLOGICAL JEALOUSY is a clinical problem that can appear in widely varying forms, contexts, and intensities (1–4). In the course of our clinical work with three couples during the past two years, a provocative and unexpected finding emerged that we think sheds light on the etiology and structure of at least one form of pathological jealousy as well as possible psychotherapeutic approaches to the syndrome.

It is somewhat difficult to designate this form of jealousy because, although many classifications of the syndrome have been proposed (5–12) (see table 1), none has gained wide consensus. We prefer to divide the pathological disturbances of jealousy into three categories: excessive, obsessive-delusional, and ego dysfunctional. All three of the patients we are reporting on here fell into the obsessive-delusional group; i.e., these patients had no obvious severe disturbance of ego function but obsessively or delusionally harbored the persisting notion that their spouses were sexually unfaithful.

CLINICAL FEATURES

The clinical form that obsessive-delusional jealousy takes is quite consistent. The central dominating symptom is a preoccupation with the conviction that the spouse is sexually unfaithful. Two accessory symptom patterns are generated from this source.

First, there is an almost constant harassment of the spouse, which takes the form of meticulous observation and reflects a watchful vigilance for any sign of the suspected infidelity. This observation may extend to the most absurd trivia of the spouse's personal life.

Second, there is an alternating cycle of rage and remorse. Actual physical assault is not unusual, homicide is a real risk, and physical destructiveness of one form or another tends to be the rule. These periods of rage seem to cycle with periods of despondency and, often, abject remorse. The patient is contrite and sorrowful and begs forgiveness. It is during this period that suicide becomes a risk.

FORMULATIONS OF PSYCHOPATHOLOGY

Studies of pathological jealousy have been either descriptions of a variety of precipitating, releasing, or circumstantial factors thought to be associated with the onset or exacerbation of pathological jealousy or elucidations of psychodynamic processes thought to be involved in the genesis of the disorder.

The first line of investigation has implicated a wide variety of factors, such as normative life crises (13), a vaguely defined jealous predisposition (2, 3), impotence (14), feelings of inadequacy and insecurity (15), and several others (16, 17).

Along the second line of investigation, a number of intrapsychic mental processes have been implicated (18). The major formulations have been the displacement of oedipal wishes (19–22), the projection of homoerotic or heteroerotic impulses (6), and oral sadistic fixation (23–26).

However, despite the overwhelming social and interpersonal consequences of this syndrome (4, 13, 16), almost no formulations have been made that systematically address transactional aspects of the disorder. In general, our present understanding of the psychopathology of this syndrome is limited.

NEW FINDING

For the last two years we have been treating three couples whose chief complaint was obsessive-delusional pathological jealousy in the husbands. A striking coincidental finding has emerged in these couples

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Docherty and Ellis*	Excessive	Obsessive-delusional	Ego dysfunctional (functional, toxic, and dementiform conditions)

* Reported in this paper.

during the course of treatment. We feel that this finding helps advance our understanding of the etiology, psychodynamics, and transactional structure of this syndrome. The jealous husbands' accusations formed a coherent pattern, but one that diverged noticeably at points from a realistic picture of their wives. In fact, the accusations more appropriately fitted the patients' mothers. In all three cases, it emerged that the husband had witnessed his mother engaged in extramarital sexual relations during his early adolescence.

CASE REPORTS

Case 1. Mr. and Mrs. A had been married for 27 years. Mr. A was 47 years old, his wife was 41, and they had three children aged 10 to 15. They came for treatment at the insistence of Mrs. A, who, having finally established a rewarding life outside the home, found the marital situation more and more intolerable.

They initially presented as a family in avalanching disarray. Both Mr. and Mrs. A had begun to drink heavily, and their sexual relationship, which was never very good, had terminated entirely. All of the children were doing poorly in their schoolwork, and the couple's fights had become more frequent and more violent. A core issue in these fights was Mr. A's condemnation of Mrs. A for alleged sexual infidelities.

Before they were married, Mr. A regarded his wife-to-be as a saintly virgin. Shortly after they were married, however, he began to accuse her of being unfaithful to him. These accusations greatly intensified during her first pregnancy and were repeated with each subsequent pregnancy. During each of the pregnancies Mr. A was convinced the child was not his. As time went by, his accusations and restrictions of Mrs. A increased: he monitored her telephone calls and examined her purse, and he would berate her until she would kneel at his feet and beg him to believe and trust her. At times, however, he would become contrite and self-accusatory and plead with her not to be angry with him. Then he would perceive some flirtation and the cycle would begin again.

During the course of treatment we began to see that some of the recurrent accusations Mr. A made about his wife simply did not fit. For example, he accused her of drinking, but when we examined this we found that, although she drank episodically (usually when she had a severe altercation with Mr. A), there was no evidence to support the belief that she was a daily drinker. Mr. A's mother, however, was well-known for her alcoholism; on more than one occasion Mr. A had had to go to town to pick up his intoxicated mother.

Mr. A also accused his wife of sexually consorting in an indiscriminate way with all sorts of undesirable characters. When we examined this we found that the only reasonably suspicious partners for Mrs. A's alleged infidelity were all respectable men. Mr. A's mother, however, had taken a job as a waitress when he was a young adolescent and had fraternized with various unsavory customers.

Having noticed these discrepancies, we pursued the matter further with Mr. A until he recalled a memory of great emotional charge. When he was 12 years old, he returned home unexpectedly early one day and found his mother engaged in sexual intercourse with a strange man. He was enraged at what he regarded as her betrayal of him and felt tremendously divided loyalties between his mother and his father. He resolved to say nothing even though his mother's affairs became the subject of violent arguments between his parents. This left him feeling bitter resentment toward his mother and guilty disloyalty toward his father.

Case 2. Mr. and Mrs. B had been married for 2 years; they had lived together for approximately 1 year before they were married. Mr. B was 36 years old; his wife was 31. This couple came for therapy after an incident in which Mr. B had become enraged at his wife for suspected infidelities. He had been drinking heavily and became physically abusive.

Almost from its beginning, this couple's relationship was plagued with Mr. B's suspiciousness. There were indications of his jealousy even before their marriage, but Mrs. B was not fully aware of the extent of his preoccupation and concern. She soon learned, however, to be extremely cautious in her interactions with other men. Mr. B demanded, for example, that at a party Mrs. B should be with him or with other women but never with other men. He needed to know her whereabouts at all times, and any unexpected change in her plans could throw him into a jealous rage. At those times, he would begin to drink, which led to even more bitter haranguing and persistent interrogation of his wife.

During treatment, we noticed a phenomenon in Mr. B similar to the one that occurred with Mr. A. Mr. B accused his wife of being grossly negligent in her household duties, but when we examined this matter in concrete detail we found that this was a highly inaccurate appraisal. It did, however, fit Mr. B's memory of his mother. This led us to pursue the question of his mother's sexual activities. With confusion and angry resentment, Mr. B recounted that when he was a young teenager his mother began to frequent a neighborhood tavern. He recalled calls from the bartender to take her home and remembered seeing her there with other men. He also recalled with bitterness a time when he came home from school and found her engaged in sexual activity with one of

the men from the tavern. Like Mr. A, Mr. B did not divulge this information to his father, although he felt terribly conflicted. From that time on he tried to cut himself off emotionally from his mother.

Case 3. Mr. and Mrs. C were both 42 years old. They had been married for 23 years and had five children. Through most of the years of their marriage, jealousy posed little problem. In fact, Mr. C paid little attention at all to Mrs. C. Three years before they came for treatment, however, things changed. Mrs. C joined a weight-reducing program, changed her style of dress, and began to look considerably more attractive. Mr. C showed signs of increased interest in her, but it took the form of mockery and growing jealous preoccupation.

Mr. C struck up an acquaintance with a man whom he began to refer to as his "best friend." He began to bring this friend home and leave him alone with his wife. Finally, he planned a trip to Florida with his wife but at the last moment stated he could not go and insisted that this friend go with her instead. Notably, the friend had recently been released from jail following a conviction for a sexual morals offense. On their return from Florida the man informed Mr. C that Mrs. C and he had had sexual relations while on the trip. Mr. C was beside himself with anger and hurt. He began to verbally attack his wife in the most vile and derogatory way. He was convinced that she was having affairs with other men. He followed her, had the telephone disconnected, and took away her car. He also continually questioned her, wanting her to tell him why she had slept with his friend. No explanation satisfied him. He began to drive his wife to distraction and himself to desperation.

We asked Mr. C about infidelity on the part of his mother. He reported that his mother had had extramarital affairs and that he became aware of this in a singularly dramatic and disturbing way when he was 14. One day he returned home after having been sent shopping by his mother and found her engaged in sexual intercourse with a man he regarded as his father's best friend. He was shocked and disgusted, but he never told anyone about the incident until he recalled it with us in therapy.

DISCUSSION

We feel that the striking and unexpected finding that three men with pathological jealousy had seen their mothers engaged in sexual infidelity when they were young adolescents is important in furthering our understanding of the obsessive-delusional form of pathological jealousy. We therefore examined the relevance of this finding to the etiology of the syndrome, the intrapsychic and transactional aspects of its structure, and possible psychotherapeutic interventions.

Etiology

The phenomenologic work on pathological jealousy has tended to implicate a wide variety of releasing or facilitative states in the genesis of this syndrome, but it has not revealed any specific factors. Psychodynamic formulations have also been broadly general. Our finding, however, holds the possibility of providing a specific etiologic factor for at least some cases of obsessive-delusional jealousy. It provides clear continuity between the patient's symptoms and his life experience.

Our speculation is that the patient is unable to integrate the specific categorical trauma of the mother's sexual infidelity. Under provocative or exciting circumstances, therefore, he deals with the trauma by means of the syndrome of obsessive-delusional jealousy. We refer to the mother's infidelity as a categorical trauma because we suppose that actually witnessing it is probably not necessary and that one isolated event is probably not sufficient; strong fantasies of maternal infidelity elicited by a seductive or flirtatious parent may also be effective causes.

Intrapsychic Aspects

It is not hard to imagine why a mother's sexual infidelity would have a pathological outcome in her son. Even on the most superficial level this event might be expected to be sufficiently discordant and to produce sufficient anxiety to foster dissociation from the major stream of mental life. This behavior is extraordinarily threatening to the integrity of the family group and introduces numerous survival anxieties. Much more to the point, however, are the probable harmful effects of such an event on the young adolescent boy's oedipal complex. This would be expected to be particularly powerful because early adolescence is normatively characterized by an oedipal resurgence. We might therefore expect a marked intensification of the fantasies of and drive toward oedipal fulfillment because the mother has demonstrated that she can be sexually available to someone other than the father. The traumatic event gains even greater power by fitting almost precisely the form usually taken by the family romance fantasies during this developmental epoch (27, 28).

We believe that one source of the aggression that characterizes the pathological jealousy syndrome is derived from two other vicissitudes of the same traumatic event. First, although the mother appears to be more available sexually to the patient, she is not actually. This constitutes in effect a tease. Second, but perhaps more important, the rage that the son feels at being second best in the oedipal situation is exacerbated in a more serious, profound, and damaging way. Now he is not only second best to his father but to strange men who have no valid claim on his mother at all. By cuckolding the father the mother makes him second best. Thus the son is unable to use an identification with the father to achieve preeminence. He is doomed unalterably to second-rate status.

We would expect the rage from this source to be enormous; we would also expect a strong drive to undo such a situation; and we hypothesize that it is this drive which lies behind the compulsive, baseless accusations of these patients and their curious avoidance of situations that might provide positive proof for their suspicions (15, 16). Thus they are able to introduce doubt and undo in some measure that terrible reality. Our observations strongly support this line of deduction, although our clinical material does not permit

confirmation in complete detail.

In addition to the issues already mentioned, there is yet another interesting speculation concerning the effects of our finding on the oedipal complex. Noteworthy in our clinical material is the very similar, almost stereotyped description each of the three men gave of his father. The fathers were almost uniformly described as passive, hardworking, long-suffering, and nurturant. The patients said their fathers were the parent with whom they had the greater conscious affectionate ties. This might well suggest a strengthening of the negative oedipal complex in these men, which might help explain the presence of an important homosexual component in patients with obsessive-delusional jealousy, albeit a less malignant component than that found in some cases of ego dysfunctional jealousy.

Transactional Aspects

Our finding suggests the operation of projective transference distortion in obsessive-delusional jealousy. One of the most cogent formulations of this process has been given by Framo (29), who described it as involving an intimate relationship in which a split-off or disavowed part of an internalized object relationship is imposed on another person. The subject relates to the other person as the projected internal object and attempts to force the other person into becoming that object (30–32).

This process stood out in bold relief in the attempt by the three husbands we treated to live out with their wives the previously unexpressed aspects of their highly conflicted oedipal relationships with their mothers.

This formulation has important implications for our clinical understanding of this disorder. It brings more obscure aspects of the syndrome into better focus. For example, the curious and remarkable endurance of the wives in the face of the husbands' fanatical jealousy becomes understandable. Laing (32) noted the compelling, almost ineluctable force of projective transference distortion. Its effect is to produce what Framo termed a "transference fix" (33). The reason for this force has not been made clear by psychological investigation. We speculate that the projective transference distortion acts as a narcissistic trap. It severely wounds the self-esteem of the recipient and elicits the assumption that repair is possible only by changing the projection. This acts as a kind of Chinese handcuffs. The more the recipients struggle to free themselves, the more deeply enmeshed in the transference relationship they become.

Implications for Psychotherapy

We feel that recognizing the presence of projective transference distortion in the structure of the pathological jealousy syndrome represents a major new perspective for psychotherapy. We agree with Lloyd and Paulson (34) that unrecognized projective transference distortion between a married couple poses an almost insurmountable resistance to therapy and may account for the therapeutic nihilism that has been expressed about this syndrome.

More optimistically, recognizing the presence of this process is a positive indication for certain obvious therapeutic interventions. The therapist should carefully develop an understanding of the distorted images the spouses hold of one another. The demonstrable differences between the actuality of the mate and the projected images should then be clearly and repeatedly identified. Further, the therapist should be aware and make use of the fact that as the therapeutic relationship grows the therapist's perceptions of the husband and wife will serve increasingly as a countervailing force against the pull to conformity with the transference distortion. This seems to allow the partners to display novel behavior within the therapy session that is at variance with the transference expectations. Much therapeutic gain can be made by attending to the emergence of discrepant behavior. This formulation also insists that therapists attend to the details of the accusations of the jealous husbands because these details will allow more effective and accurate reconstruction of the disavowed relationship and thus enhance its reinternalization.

Finally, our analysis suggests a rational basis for the difficult question of the simultaneous use of multiple modes of treatment. A clear but interdigitating difference in the tasks of individual and couples treatment is indicated. Couples treatment would seem to be the preferable mode for the analysis of the projective transference distortion and the reciprocally interlocking circuit that gets set up around it. Individual therapy would seem a more efficient and effective mode for a full exploration and resolution of the conflicted oedipal relationship of the husbands.

Treatment for the Parents of Feminine Boys

BY LAWRENCE E. NEWMAN, M.D.

Because extreme boyhood femininity is often a precursor of adult transsexualism, transvestism, and homosexuality, the author recommends early intervention for boys who meet specific behavioral criteria of gender disturbance. It is necessary to involve the parents in such treatment and to deal with the resistances they may have to recognizing and working on the problem as well as problems within the marital relationship that may affect the child's behavior. These boys are remarkably responsive to treatment given between the ages of 5 and 12, becoming more masculine in behavior and more comfortable with their identity as males.

YOUNG BOYS who behave like girls have been the subject of increased clinical concern in recent years. There is evidence that boys with pronounced feminine behavioral patterns do not necessarily become masculine with time. In many cases boyhood femininity is a precursor of transsexualism, transvestism, and homosexuality. This was first suspected because almost all adult male transsexuals and many homosexuals and transvestites gave histories of dressing up as girls and pretending to be women in their play as children (1–4).

Prospective studies lend support to these clinical reports. Green (5) conducted longitudinal studies of 5 feminine boys. As adults, 3 had become homosexual, 1 refused an interview but was reported by his family to collect photographs of nude males, and 1 reported sexual arousal when putting on feminine underpants, although he had not cross-dressed since age 6. Lebovitz (6) found that of 16 adult males who had been considered feminine in childhood, 3 were transsexuals, 2 were homosexuals, and 1 was a transvestite. Zuger's follow-up study of 6 feminine boys into adolesence indicated that 3 were homosexual and 1 was transsexual (7). Thus, evidence from recent studies indicates that feminine boys are a high-risk group for adult gender identity disorders.

Dr. Newman is Adjunct Assistant Clinical Professor, Department of Psychiatry, University of California School of Medicine, 760 Westwood Plaza, Los Angeles, Calif. 90024.

POSTPUBERTAL GENDER DISORDERS

Gender identity aberrations seem to crystallize during puberty, becoming essentially irreversible (8). Despite the efforts of therapists working with various methods, reports of real change in adolescent or adult transsexualism are very rare (9–11). Barlow and associates (12) reported one case of gender reorientation by behavior therapy in an adolescent transsexual. Other reports of gender reorientation of transsexuals, however, describe individuals who began treatment with evidence of significant preexisting masculinity. We recently described a number of men who initially insisted on reassignment surgery but gave up this wish after psychotherapy (13). These men did not manifest exclusively feminine lifelong interests, nor was there a total absence of masculinity in their adult lives. They had suddenly seized upon the idea of sex change as a magical solution after a crisis such as loss of a homosexual lover or schizophrenic decompensation. Truly transsexual males, in contrast, feel like women continuously. They have given up any desire to be accepted as males and have no motivation for treatment to alter their feminine orientation. However, many do recall wishing for acceptance as boys in childhood; they often report that this desire was then as strong as their feminine feelings. During adolescence, they give up the wish to be accepted as a male by others. Sex reassignment for these males as adults is a palliative treatment in which the body is altered to fit the mind because the individual is no longer able or willing to change his mind to fit his body. Therapeutic results with other gender disorders, such as transvestism and effeminate homosexuality, is also poor, suggesting that these less severe gender misorientation patterns also become fixed after puberty.

RESPONSIVENESS TO EARLY INTERVENTION

Feminine boys, unlike men with postpubertal gender identity disorders, seem remarkably responsive to treatment. Feminine boys treated between the ages of 5 and 12 gradually become less feminine and more masculine (14–17). Cross-dressing and feminine fantasy play diminish rapidly and the boys become more verbally and physically aggressive toward their mothers in almost all reported cases. Teasing and social rejection by male peers decreases and is replaced by acceptance. During the initial 12–24 months of treatment, these patients begin to enjoy being accepted as boys, and their acceptance is a strong, continuing reinforcer. Improvement has been achieved with a variety of different approaches, including daily psychoanalytic play therapy (14, 17), behavioral therapies (15), and individual therapy for the child combined with counseling for the parents, either individually or in groups (5). We reported the results of 4 years of treatment of 5 extremely feminine boys. Treatment consisted of once or twice weekly individual play therapy with a male therapist and parent counseling (18). All of these boys became more masculine, more aggressive, and discontinued their specifically feminine behaviors (e.g., cross-dressing).

The dramatic results that can be achieved are noted in Rekers and Lovaas' discussion of the case of a very feminine little boy treated with a behavioral approach.

> When we first saw him, the extent of his feminine identification was so profound (his mannerisms, gestures, fantasies, flirtations, etc., as shown in his "swishing" around the home and the clinic, fully dressed as a woman with a long dress, wig, nail polish, high screechy voice, slatternly, seductive eyes) that it suggested irreversible neurological and biochemical determinants. After 26 months follow-up, he looked and acted like any other boy. People who viewed the video taped recordings of him before and after treatment talk of him as "two different boys." (16)

Some of the boys treated in childhood have now become adolescents and remain masculine. None are reported to have reverted to cross-dressing. Transsexualism no longer seems likely for any of them. However, their future choice of sexual objects remains unknown.

Acceptance by same-sex peers in childhood replaces ostracism with a happier existence. They no longer need to withdraw into the feminine fantasy world and are capable of giving up this world voluntarily.

It seems evident that the treatment of choice for gender identity disorders is primary prevention in childhood. No matter how dramatic the femininity of a prepubertal child may be, the evidence indicates that his gender orientation has not yet crystallized. These patterns are not fixed by the third year of life (19).

FAMILY PATHOLOGY

It is fortunate that very feminine boys have behavioral patterns that are easily identified. However, these obvious signs do not always lead the families of boys at high risk to seek help. It is not unusual for parents to shield, tolerate, and rationalize the boy's cross-dressing for years. Mothers generally fear losing the son's companionship as he becomes more masculine and are therefore reluctant to begin a treatment program. The fathers generally resent and avoid their feminine sons.

Both parents tend to find rationalizations for avoiding professional help. The most common are: 1) the problem is being exaggerated and is actually much milder than the person who has pressured the parents to seek help believes it to be, 2) it will go away with time, 3) evaluation or treatment might in some way damage the child's sensitive nature or paradoxically make matters worse by "making the child think about it more," and 4) the feminine son is "destined" to become a homosexual (or other very feminine male) regardless of any intervention, so why bother? Fathers

who employ such rationalizations avoid their sons, which compounds and sustains the problem. The mother's "tolerance" really means insulating her son from the insults of siblings, father, or schoolmates by building a tight cocoon in which he can indulge his feminine play. She is being tolerant not of her son but of his pathology, and is indulging her need for his dependency and companionship.

In evaluating an extremely feminine boy, one should anticipate such parental rationalizations and search for them even if they are not openly expressed at first. They must be effectively countered during treatment. In the rare case in which there is no covert parental resistance, therapeutic change may occur with extraordinary speed (18).

THE EVALUATION PHASE: DECIDING WHETHER TO TREAT

Critical assessment of the parental description of the boy's gender role behavior, past and present, precedes direct assessment of the child in the playroom. I believe that it is useful to divide these behaviors into two categories and that treatment is not indicated for a complaint of boyhood femininity unless one or more behaviors from the first category are described. These first-category behaviors are those which, if continued into adult life, would make up the clinical picture of adult transsexualism.

1. Cross-gender clothing preferences (wearing girl's dresses, putting on the mother's shoes, wigs, makeup, or jewelry, or creating dresses or skirts out of towels or other materials).
2. Verbal statements expressing the wish to become a girl or to grow up to become a woman.
3. Taking female roles in fantasy games such as that of actress, mother, grandmother, or witch, while protesting if given the role of a boy or man.
4. Imitating the gestures and mannerisms of a woman, including exaggerated swaying of the hips, effeminate gait, feminine inflection of speech, etc.

These major (pretranssexual) behaviors generally are found together with the following "minor criteria" behaviors. However, if no major criteria behavior is present, significant gender pathology is probably not present.

1. Dislike and avoidance of rough, competitive boys' games.
2. Dislike of mechanical toys such as trucks, metal airplanes, construction equipment, etc.
3. Preferences for artistic activities (painting or listening to music) or for other sedentary activities.
4. Enjoyment of girls as playmates.
5. Gracefulness in bodily movements and gestures (to be contrasted with the exaggerated imitation and mimicking of the behavior of women that is a major behavioral criterion).
6. Reports of being teased as a "sissy" by other boys.

Without the presence of the first-category behaviors, these behaviors do not reflect gender pathology. Each reported behavior should be evaluated for intensity (emotional importance to the child) and duration; a behavior that occurs only once or twice and is willingly given up does not fulfill a criterion. The description earlier in this paper of the boy treated by Rekers and Lovaas (16) is typical of the truly feminine boys who meet at least one and perhaps all of the major criteria described previously.

Not infrequently, evaluation is requested by parents for boys who meet none of the major behavioral criteria. These parents may require only a careful hearing and reassurance. Such reassurance relieves the parents' anxiety and helps to prevent the negative impact that their doubts about the child's masculinity can cause. For example, the parent who believes that his/her son is not masculine solely because he avoids rough games and prefers reading or painting may be subtly harming the boy's sense of worth.

The parents' reports of the boy's behavior are essential to making the diagnosis of boyhood femininity and determining whether treatment is necessary. These reports must then be followed by playroom evaluation of the child, in which his gestures, choice of play materials, and fantasies expressed in play are observed and assessed (5).

THE TREATMENT PHASE

It is essential that the therapist enlist parents' support and commitment to the lengthy treatment endeavor. The therapist has to bring into the open and fight the nihilism of the parent (usually the father) who feels that his son is already a homosexual or worse and wants nothing to do with him. He must also counter the ambivalence of the mother, who may express the fear that treatment will upset her son and make him unhappy. Mothers may feel that because the son has so little else (no boy friends, girl friends whose parents dislike him, ostracism at school), it would be cruel to deprive him of his feminine activities. They may covertly supply him with feminine play materials after treatment starts because they do not want him to be sad. They are also satisfying their own need to keep the boy emotionally close by such activity.

The case of a very feminine 10-year-old boy is illustrative.

CASE REPORT

The parents brought the child for evaluation only after the pastor of their church observed the boy's feminine ways and love of makeup when he was in a church play. The boy had cross-dressed for at least six years with his mother's knowledge. The father expressed the feeling that his son was a "fag," which drew a startled and angry look from the mother but no protest. The father loved to hunt and fish and was therefore away from home almost every weekend. He said

he had tried to take his son along but "gave up" because the boy did not seem to enjoy the activity. The boy felt that his father hated him. He usually stayed in his room when his father was at home to avoid encountering him. The boy's symptoms included frequent cross-dressing, effeminate posturing, and the wish to become a woman.

Throughout treatment, sessions with the mother were necessary to help her accept the emotional loss of her son as he became more outwardly aggressive and began to express hostility toward her for the first time. The mother was a lonely woman who had tolerated the emotional and physical absence of her husband much of her married life. Shopping with her son was one of the few high points in her day, and in the course of the treatment he turned against this activity. She disliked giving up the companionship of her son on visits to the beauty parlor, an outing he had previously loved.

Sessions with the mother sometimes dealt with the meaning of masculinity and femininity. The mother secretly hated what she then thought masculinity was—a mixture of brutality, sexual license, and boorishness. These had been qualities of her own hated father, and she felt they were also characteristic of her husband. She preferred boys who were "gentle" because she feared that the "other kind" would grow up to become "selfish, mean men." She had discouraged any signs of assertiveness or aggressiveness in her son and often expressed to him her hatred for the "nasty" boys in the neighborhood. Her son loved her more than he loved his father, she reported with some pride, as if it were a contest.

After 15 months of treatment the boy, who had become much less effeminate in his mannerisms and had drawn away from his mother, seemed to regress, and the mother seemed to be hiding something. She resented my asking her what was making her uneasy, and angrily replied that nothing was wrong. Shortly thereafter the son revealed to me that he had for the last two months been wearing a pair of his mother's high-heeled shoes in the house when his father was not home. When confronted with this, the mother admitted in her session that she had given the shoes to her son because "I was all through with them anyway and he always used to admire them so. I felt, well—I'm going to be throwing them away anyway, so why shouldn't he have them?" With help, she was able to see that her behavior had been an effort to sabotage the treatment. She had difficulty facing this fact when it was openly stated and felt very guilty. This enabled her to begin to work more seriously on her fears of losing her son's companionship and on her hatred toward her husband and father and her fear that her son was going to become "just like them." The son rapidly became more assertive and less dependent on his endless solitary hours of feminine fantasy play. He began to make friends with other boys for the first time in his life, but preferred sedentary activities.

During this phase of the treatment it was possible to enlist the father's help. Up to that point he had not been able to "find the time" to come see me. Encouraged by his son's clinical improvement, the father again offered to take him on fishing trips, and the boy now accepted. The shift in family dynamics, with the mother no longer demanding (or needing) the son's total involvement and the father's new acceptance of him enabled his gender role behavior to move rapidly in a masculine direction.

This case report is illustrative of several issues that the psychiatrist should anticipate in approaching the parents of a very feminine boy. Of greatest importance is the mother's covert dependence on the unique emotional relationship with her feminine son, which makes her ambivalent toward the goals of treatment. In addition, she may be genuinely confused about the "definition" of masculinity and femininity and associate masculinity with ugly and insensitive behavior. She needs help in tolerating her son's initial unhappiness when he is told not to cross-dress. She will also need help in recognizing and reinforcing specifically masculine behaviors while negatively reinforcing specifically feminine behaviors such as cross-dressing. Treatment in which the boy is secretly allowed to cross-dress at home is only a training in deception, yet it does occur.

Sometimes the parent's uncertainty about the definitions of masculine and feminine behaviors comes from confusion about his/her own gender role. When this problem is pronounced, psychotherapy for the parents is indicated.

A further important goal in working with the parents of feminine boys is to improve the marital relationship—schisms between the parents are apparent in almost all cases. Gender aberration is extremely unlikely when love and sexual pleasure are present in the parents' marriage. Treatment for the parents aimed at overcoming their distance from each other is a powerful tool in freeing the child from the family scapegoat role in which he has been trapped.

THE POSTTREATMENT PHASE

When the boy has become normal in his behavior for a period of at least six months, continued psychiatric treatment is no longer necessary. However, contact with the parents should be maintained continuously thereafter in order to ensure that the pathological family dynamics do not reassert themselves, bringing about a regression.

How is it possible for dramatic changes in gender orientation to occur as a result of treatment in childhood? Extremely feminine boys do not seem to develop normal oedipal conflict prior to treatment (19). Evidences of oedipal tension, especially incestuous feelings, castration anxiety, and identification with the parent of the same sex, are not seen. Without treatment, the preoedipal feminine orientation of the boy develops in an undistorted form and in adolescence he has a growing conviction that he must become female, thus creating transsexualism.

With treatment (i.e., the intervention of a masculine therapist who is respected and perhaps feared by the mother), oedipal conflict becomes evident. Pride in being a boy appears for the first time along with increased aggressiveness toward the mother, breaking their symbiotic tie. This is the same kind of behavior observable earlier in normal masculine boys during the oedipal phase. The male therapist initially substitutes as a friendly role model for the patient's own father, who is, almost invariably, a distant, unavailable, and often hostile figure.

ETHICS OF TREATMENT FOR FEMININE BOYS

Is it right to attempt to alter the behavior of the very feminine boy? Some who do not view homosexuality or even transvestism and transsexualism as illnesses argue that it is wrong to intervene. Others may argue that treatment for very feminine boys, although perhaps successful in replacing femininity with masculinity, does not necessarily alter future choice of sexual objects. The very feminine boy may not become a transsexual (as some do without treatment), but may instead be homosexual. Is one clinical state better than the other?

I believe that treatment *is* indicated for the very feminine boy. The preference for feminine behaviors seems to be based upon a deficit in learning masculine behaviors from an appropriate model. Once the therapist provides this model, identification occurs, new behaviors are learned, and the feminine behaviors are gradually given up. Even if the boy does not then become completely masculine, the reduction in overtly feminine gesture and play preference makes him acceptable to boys who previously teased and avoided him. Experiences of being ostracized and ridiculed may play a more important role than has been recognized in the total abandonment of the male role at a later time. With treatment, behavioral change, and a new acceptance by his male peers, the child gains in self-worth, which seems to influence the long-term outcome. Treatment should be directed not at turning the feminine boy into an athlete or suppressing his aesthetic yearnings, but rather at developing his pride in being male. A happier childhood as well as primary prevention of an adult gender identity disorder are two related goals of treatment.

ECT in the Treatment of Mania: A Controlled Study

BY MICHAEL S. MCCABE, M.D.

In a chart review study of manic patients, the author found that ECT remarkably improved outcome variables of condition at discharge, duration of hospitalization, and social recovery in comparison with an untreated matched control group. More conclusive evidence would depend on a prospective trial with random assignment of manic patients to ECT, lithium carbonate, and major tranquilizers and blind evaluation of outcome.

RECENT LEGISLATIVE, social, and legal developments have resulted in serious constraints being placed on the use of electroconvulsive therapy in psychiatric practice. *Psychiatric News* has covered legal developments in California and Alabama in detail (1, 2). When major constraints are placed on the use of specific forms of treatment, it is imperative that claims for the effectiveness of these treatments be based on firm scientific ground.

Most reports on ECT as a treatment for manic-depressive psychosis deal with depression alone (3–6) or are anecdotal with regard to the treatment of the manic phase of bipolar (manic-depressive) psychosis (7–10). Two early studies (3, 11) employed controls. The study by Ziskind and associates (11) included manic episodes but used 14 treated patients and only 6 untreated controls. Treatment results were excellent (86% recovered at follow-up), but the number of controls was too small for statistical analysis. The careful study by Huston and Locher (3) used an untreated control group but specifically excluded patients with manic episodes. The paucity of controlled studies of ECT in the treatment of mania suggested the need for a companion report to the investigation by Huston and Locher. Consequently, I am presenting the results of a chart review study of ECT in the treatment of mania with untreated controls.

Dr. McCabe is Assistant Professor, Department of Psychiatry, State Psychopathic Hospital, University of Iowa, 500 Newton Rd., Iowa City, Iowa 52242.

The author would like to thank George Winokur for suggesting this study.

METHOD

Treatment Group

ECT patients were selected from consecutive admissions to the Iowa Psychopathic Hospital during the years 1945 through 1949 with a hospital diagnosis of manic-depressive:manic or manic-depressive:mixed. Symptoms of mania required by the "Diagnostic Criteria for Use in Psychiatric Research" (12) had to be documented in the hospital record. These diagnostic criteria are euphoric and/or irritable mood and at least three of the following symptoms: hyperactivity (including motor, social, and sexual activity), pressured speech, flight of ideas, grandiosity, decreased sleep, and distractibility. The syndrome had to be of at least 2 weeks' duration. Patients with a prior diagnosis of organic brain syndrome, mental retardation, schizophrenia, alcoholism, anxiety neurosis, obsessive-compulsive neurosis, hysteria, drug dependency, or antisocial personality were excluded. Thirty-two patients in the specified time period met the diagnostic criteria for mania: the 28 who were treated with ECT constituted the treatment group.

Control Group

Controls were selected from consecutive admissions to the Iowa Psychopathic Hospital from the period 1935–1941 and were matched to the ECT group on the basis of age and sex. The age difference between ECT patients and their matched controls did not exceed 3 years. The selection of controls was blind as to outcome. Data on a larger group of manic patients from which the control group was selected were reported in "The Iowa 500" (13). Diagnostic criteria in the control group were the same as those cited for the ECT group.

Procedure

Data collected for both ECT patients and controls included age, sex, marital status, length of episode at admission, prior admission, duration of hospitalization, type of discharge, condition at discharge, social recovery, subsequent episodes, family history, number of treatments, and clinical symptomatology. The quality of follow-up information has been discussed previously (13) and is based on letters to other hospitals, families, or private physicians, and interviews by social workers. Follow-up information for at least 6 months was available for all subjects except 3 control cases who were transferred to other hospitals. Statistical analyses were done by Fisher's exact test, except duration of stay, which was compared by an independent t test. A probability not exceeding .05 was required for statistical significance.

RESULTS

Demographic Data and Prior History

The ECT and control groups consisted of 17 women and 11 men each. Mean age was 33.5 years in the ECT group (range, 17–57) and 33.6 years in the control group (range, 18–58). The mean number of ECT treatments was 17, with a range of 6–32. Eleven of the patients required more than one series of treatments. Seventeen of the ECT group were married at the time of index admission compared with 15 of the controls (p=n.s.).

Symptomatology

Table 1 presents a comparison of the frequency with which different symptoms were noted in the two groups. As would be expected in patients selected by identical diagnostic criteria, differences are small and statistically nonsignificant. The most frequent symptoms were those required by the diagnosis.

Outcome

Follow-up information for at least 6 months after discharge was available for all subjects except the 3 controls who were transferred to other hospitals. Follow-up covered a mean of 5.2 years in the ECT group and 3.1 years in the control group. This difference appeared to reflect a greater tendency for patients to return to the same facility for treatment of subsequent episodes of illness during the years when ECT was available than was observed before the availability of ECT.

Results for category of discharge, duration of hospitalization, and last known outcome are given in table 2. Discharge condition, taken from the physician's discharge summary, was rated worse, unimproved or unchanged, mild or slight improvement, marked improvement, or well. (These ratings were collapsed for the statistical analyses.) "Worse" and "unimproved" are considered self-explanatory. "Mild improvement" was applied to those patients who experienced diminution of intensity of symptoms but who could be characterized as hypomanic and not delusional. "Marked improvement" was applied to patients who demonstrated no manic symptomatology at discharge. The term "well" was erratically applied. In the ECT group the breakdown was as follows: unimproved, N=1; mild improvement, N=4; marked improvement, N=18; and well, N=5. The breakdown in the control group was as follows: unimproved, N=15; mild improvement, N=3; marked improvement, N=9; and well, N=1. The principal difference between the two groups centers on the numbers of patients who were considered markedly improved or well: 23 patients from the ECT group (82.1%) were in these categories compared with 10 (35.7%) in the control group. Duration of hospitalization was defined as the total period of hospitalization for the index episode, including the time after transfer to another facility. The category "last known ill" includes 4 deaths in the control group; all occurred during the index manic attack. In 3 cases the description appeared to indicate fatal exhaustion. The fourth patient died of pulmonary embolism following a venous thrombosis in the thigh due to an improperly placed binder. No patient in the ECT group died dur-

ing a manic episode. The numbers of deaths in the two groups were not significantly different (p=.056).

DISCUSSION

This investigation used an untreated control group to study ECT in the manic phase of bipolar affective disorder. With the development of effective treatment methods such as lithium carbonate and major tranquilizers, it has become increasingly difficult to justify ethically the use of a placebo control group. This investigation circumvented that ethical problem by selecting controls from a period in which there was no effective treatment available for mania. Such an investigation can be performed only where records reflect standards of excellence over a period of many years; the Iowa Psychopathic Hospital has maintained such a tradition.

Although ECT patients and controls were selected from different time periods, illness variables that might have been expected to affect outcome proved to be remarkably similar. Age, sex, and diagnosis were controlled. Marital status, prior episodes, and duration of episode prior to admission were almost the same in the two groups (no comparison was statistically significant). Similarly, symptoms used in diagnosing mania were virtually the same in the two groups. There were no significant differences in the various types of hallucinations and delusions recorded for the two groups. Treatment and control groups were comparable in severity of illness and premorbid functioning at the time of their index admissions. Only four patients who met diagnostic criteria for mania did not receive ECT. These patients all had milder forms of the illness, and this selection bias tended to favor the control group.

The principal defect in design was that the subjects were selected from different time periods. Although all outcome measures favored the ECT group, differing expectations of physicians regarding the prognosis of the disease during these time periods might have affected any or all of the outcome variables. Had this been the case, few of the patients in the 1935–1941 period should have been described as markedly improved or well. In fact, 36% were so described. Similar arguments could also be presented for the discharge category. If the expectations were uniformly gloomy, the discharge to home of nearly half (44%) of the control group would be indeed remarkable. Discharge data from the two periods provide further information. The mean duration of stay at the Iowa Psychopathic Hospital during 1935–1941 was 37.0 days compared with 46.1 days in the period 1945–1949. This is a reversal of trends found in the current investigation for manic patients. In addition, the magnitude of the difference in mean duration of stay of patients and controls would be difficult to explain entirely on the basis of physician expectations. The most definitive way to deal with this question would be to randomly assign patients to treatment and control groups, using blind evaluation of results.

Differences in final outcome are difficult to explain on the basis of physician expectations. Social recovery was based on the report by the Social Service Department that the patient had returned to his/her premorbid level of functioning. Most important here is the finding concerning death during the index episode. Four untreated manic patients died during the index episode. With the variety of treatments available today—lithium carbonate, phenothiazines, butyrophenones, and ECT—the thought that untreated mania can be lethal arises infrequently.

The finding that 96% of the ECT group were sufficiently improved to be discharged to home suggests that ECT may be a valuable tool in the treatment of the manic episode. Previous reports dealing with the efficacy of ECT in manic-depressive psychosis dealt only with the depressive phase (3–6) or were anecdotal (7–10) and had no controls. This may reflect in part diagnostic concepts that did not distinguish between unipolar (depression only) and bipolar (mania and depression) affective illness. This report partially fills the void in the literature concerning ECT in the treatment of the manic phase of bipolar affective disorder. More conclusive evidence concerning the efficacy of ECT would have to come from a prospective trial with random assignment of subjects to ECT, lithium carbonate, or a major tranquilizer and blind evaluation of outcome.

Psychiatric Illness in Homicide Victims

BY MARIJAN HERJANIC, M.D., AND DAVID A. MEYER, M.D.

The authors studied the demographic characteristics and history of psychiatric treatment of 214 homicide victims and 67 suicide victims. Thirty-two (15%) of the homicide victims and 12 (18%) of the suicide victims had a record of psychiatric care; these rates were higher than the treatment rate of the general population. The authors suggest that there may be a connection between the occurrence of homicide and the increased frequency of psychiatric disorders among victims of this crime.

THE INCREASE in the number of homicides in urban areas has recently attracted a great deal of public attention and concern, and the voluminous literature on homicide indicates that social scientists as well as the public have a great interest in this crime. In St. Louis, the homicide rate increased from 8 per 100,000 in 1942 (1) to 33 per 100,000 in 1973, and other large cities have experienced similar or larger increases.

Early literature on murder focused on the offender, but Von Hentig (2) shifted the emphasis to the victim-offender relationship, and Wolfgang (3) pointed out that one-fourth of homicide victims had clearly precipitated their own deaths. Houts recently went even further by stating that "in a great many cases, the murderers are rather reasonable normal people, whereas the victims were the discordant individuals—at least, they possessed strange quirks of personality and character that contributed mightily to their demise" (4, p. 230).

This suggestion of psychological aberrations in homicide victims raises the issues of psychiatric illness among victims and the potential for a contribution by mental health workers to the prevention of crimes. Because we were unable to find any systematic studies of psychiatric illness in homicide victims, we decided to examine the circumstances in which homicides occur and the general characteristics of victims, with special emphasis on victims who had received psychiatric care. We contrasted our findings about homicide victims with the characteristics of a well-studied group of individuals who also suffer violent deaths—suicide victims.

Revised version of a paper presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Herjanic is Associate Professor, Department of Psychiatry, Washington University School of Medicine, St. Louis, Mo., and Assistant Superintendent, Malcolm Bliss Mental Health Center, 1420 Grattan St., St. Louis, Mo. 63104. When this work was done, Dr. Meyer was a medical student, Washington University School of Medicine; he is now a resident in psychiatry, Washington University School of Medicine and Malcolm Bliss Mental Health Center, St. Louis, Mo.

This study was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grant MH-05938 from the National Institute of Mental Health.

The authors would like to thank Dr. A.C. Meyers, Jr., Chief Statistician, and Col. Norman Jacobsmeyer, Chief, Homicide and Arson Division, St. Louis City Police Department, for their advice and cooperation.

METHOD

There were 220 homicide victims in the city of St. Louis in 1973. Since we were primarily concerned with studying psychiatric treatment of homicide victims, 4

victims whose names were unknown were dropped from the study. Two other victims, children 18 months and 9 years old, were also dropped; thus the final study group contained 214 victims.

The circumstances of each crime were studied and coded. To find out about psychiatric care received by homicide victims, a list containing the name, sex, race, and date of birth of each victim was compared with a list of patients treated at two large state-supported institutions (Malcolm Bliss Mental Health Center and St. Louis State Hospital) that provide psychiatric care for the city of St. Louis. Victims' medical records discovered by this method were reviewed systematically and data were recorded.

Data were gathered by a similar method on all persons (N=67) who committed suicide in St. Louis in 1973. This group was used for comparison purposes.

RESULTS

Table 1 gives a summary of the study results. Men predominated in both the homicide and suicide victim groups. There were significantly more black homicide victims than suicides ($p<.001$). Homicide victims were significantly younger (average age=35 years) than suicide victims (average age=49 years) ($p<.001$, by t test); blacks were younger than white victims in both groups. Approximately the same proportion of both groups had a history of psychiatric treatment.

To determine how many former patients one could expect to find among homicide and suicide victims, we used data from one center (Malcolm Bliss Mental Health Center) that provides psychiatric care for approximately two-thirds of the total population (622,000) of St. Louis. Only homicide and suicide victims with home addresses in the catchment area of this center were used for comparison. Although only 4% (N=15,848) of the people living in the catchment area had a record of patient care at the center, 12% (22 of 183) of the homicide victims and 22% (10 of 44) of the suicide victims had been treated. The differences between the treatment rates observed for the homicide and suicide groups and the rate in the general population were highly significant ($\chi^2=28.13$ for homicide victims, 35.05 for suicide victims; $p<.001$). No significant difference was found between the rates of psychiatric care in the homicide and suicide groups.

Diagnoses

The diagnosis of each subject was taken from hospital records; no attempt was made to reach an independent research diagnosis. Alcoholism, sociopathy, and drug addiction accounted for 72% of the diagnoses of all homicide victims, with alcoholism the most frequent diagnosis (see table 2). If secondary diagnoses had been taken into consideration, 2 more victims would have been included under alcoholism, 1 more under sociopathy, and 1 more under drug addiction. All patients with a diagnosis of drug addiction had been addicted to opiates. Of the 4 homicide victims listed in table 2 under the diagnostic category "other," 1 had a diagnosis of hysteria, 1 situational reaction of adolescence, 1 inadequate personality, and 1 drug intoxication. Among the suicide victims, the patient listed under "other" had a diagnosis of hysteria.

It is interesting to note the complete absence of affective disorders among homicide victims and the rarity of other serious psychiatric illness such as schizophrenia, organic brain syndromes, or mental retardation. Since there were only 4 victims with these diagnoses, it was impossible to examine them as a separate group. However, some features distinguished them from the other homicide victims—they were considerably older (average age 53 years), and the circumstances under which they were killed were different (the two schizophrenic victims were killed by strangers in their own homes and the patient with organic brain syndrome was killed during a robbery, whereas a typical victim was killed by a friend or relative after an argument).

Suicide victims showed a different pattern of diagnoses. Fifty percent of the group suffered from affective disorders. The diagnostic distribution of suicide

victims in our study who had received psychiatric treatment was similar to the distribution found by Robins and associates (5) in a study of 134 suicides committed during 1956 and 1957 in the St. Louis area. Robins and associates (5) also found that, although almost all persons who committed suicide suffered from a psychiatric illness, only 19% were actually treated by a psychiatrist during the year prior to their deaths; in our study, 12% of the suicide victims had received psychiatric treatment during the year before their deaths.

DISCUSSION

Our method of determining the rate of psychiatric treatment of homicide and suicide victims is open to challenge, since we checked only the records of two public psychiatric institutions; other victims may have been treated instead by private practitioners or in private hospitals. A more accurate method would have been to interview the relatives and friends of the deceased victims to obtain a full psychological autopsy, for the important question is not only how many victims received psychiatric care but also how many displayed symptoms indicating a possible psychiatric disturbance and need for treatment.

We contrasted the group of homicide victims with a history of treatment for psychiatric illness with the rest of the homicide victims with regard to the following variables: sex, race, age, relationship with assailant, location of crime, drinking at the time of death, role of victim in precipitating the crime (3), place of death, weapon used, victim-offender relationship by sex, victim-offender relationship by race, and the time of day of the crime. The two groups of homicide victims appeared very similar with respect to these variables. Statistically significant differences were found for only 2 of the 12 characteristics examined—fewer victims with a history of psychiatric care had been killed by members of their own family and more were killed on the street or in their cars than victims without previous psychiatric treatment. However, in view of the small numbers in each subgroup and the low levels of significance obtained, these findings should be viewed as trends at best.[1]

CONCLUSIONS

Based on the data we gathered, the typical homicide victim was a young black male who was killed with a gun in an argument with a relative, friend, or acquaintance. In 91% of the homicides studied, victims and murderers were of the same race, and in 74% of the cases they were of the same sex. History of psychiatric treatment or absence of it did not divide homicide victims into two distinct groups.

The number of homicide and suicide victims with a history of psychiatric care was significantly higher than would be expected from study of the general population. There was a qualitative difference in the diagnostic distributions found for the homicide and suicide groups.

Although it is assumed that almost all suicide victims are psychiatrically disturbed (5), only a small proportion (18%) of suicides in our study had been treated by psychiatrists. Since the proportion of suicide and homicide victims treated by psychiatrists was similar, we wonder if we could conclude that most homicide victims are also disturbed.

Forensic Psychiatry: Profiles of Two Types of Sex Offenders

BY FRITZ A. HENN, PH.D., M.D., MARIJAN HERJANIC, M.D., AND ROBERT H. VANDERPEARL, M.D.

The authors examined records of 239 individuals charged with sexual offenses and referred by the courts to a forensic service. Defendants charged with rape were typically under 30 with histories of antisocial behavior that included other types of violence. Major mental illness was rare in this group. Child molesters in the sample were of no particular age, usually had no history of violent behavior, and had a low incidence of psychosis. The most common secondary diagnosis in both groups was alcohol or drug abuse.

THIS PAPER reports an empirical examination of the characteristics of a group of defendants charged with sexual crimes and referred to the Malcolm Bliss Mental Health Center Forensic Service for psychiatric evaluation. The study was designed to answer two principal questions: Are there distinguishing characteristics between groups of defendants charged with different sexual offenses? What role does psychiatric illness, particularly psychosis, play in sexual offenses? The results of our study of 239 defendants can be most clearly presented by reporting on the individuals charged with child molestation and rape, which were the most common charges against defendants admitted to the service.

A wide variety of viewpoints has been brought to the study of sexual offenders. To some extent, this is due to the nature of the subject itself. Sexual offenses are, in part, culturally determined and therefore value laden, and responses to them become imbedded in the legal framework. The legal responses to these offenses often reflect the fears or values of the culture rather than the characteristics of the offender. Because the offenses are related to cultural values, opinions are strong and facts are sometimes difficult to ascertain. As Guttmacher and Weihofen (1) stated over 20 years ago, "There is doubtless no subject on which we can obtain more definite opinions and less definite knowledge." However, there have been advances since that statement was made. A book by Mohr and associates (2) on child molesters and exhibitionists provided a careful evaluation of these offenders. MacDonald (3) examined many aspects of rape. Thus, comparisons of different cohorts of sexual offenders have become possible, and the facts concerning sexual offenders can be established and made available not only to psychiatrists but to all concerned with these problems.

Presented at the 128th annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Dr. Henn is Assistant Professor, Department of Psychiatry, State Psychopathic Hospital, University of Iowa, 500 Newton Rd., Iowa City, Iowa 52242. Dr. Herjanic is Assistant Superintendent and Dr. Vanderpearl is Director, Forensic Service, Malcolm Bliss Mental Health Center, St. Louis, Mo.

METHOD

We reviewed records of all defendants charged with sexual crimes and referred for evaluation to the Malcolm Bliss Mental Health Center Forensic Service, St. Louis, Mo., during the years 1952–1973. Out of a total of 1,195 cases, 239 involved defendants charged with at least one sexual crime. These cases were reviewed and coded for demographic variables, diagnosis, crime, and outcome. Crimes represent the charges against the defendant on admission to the service, and diagnoses are those given in the report to the court. The Forensic Service is responsible for all patients referred by court in the city of St. Louis and some patients (less than 10% of the total) from surrounding counties. In more than 90% of the cases, the defendant was admitted for a pretrial examination.

RESULTS

The cohort of 239 defendants had a total of 273 charges of sexual offenses. There were 69 charges of rape and attempted rape, 116 of child molestation, and 43 of sodomy. We will focus on rape and child molestation, since sodomy consists of a variety of different offenses. The other classes of offense, such as exhibitionism, were seen in only a small proportion of these defendants.

Demographic Variables

The demographic variable that most strikingly separated defendants charged with rape from those charged with child molestation was age. Those implicated in rape were much younger on the average—over 75% were under 30. Defendants involved in cases of child molestation were distributed over the entire age range—only 28% were under 30 and almost as

TABLE 1
Primary Diagnoses of 239 Sexual Offenders

Other	0	0.0	34	30.6	1	2.4	1	5.3
Not ill	6	9.0	8	7.2	5	11.9	0	0.0

many were over 50. The difference in mean age of the two groups was statistically significant ($p<.01$).

Concurrent Charges

We tabulated concurrent charges against defendants that involved violence or potential violence (i.e., homicide, robbery, and assault). Defendants involved in rape or attempted rape (N=67) had a total of 15 offenses against persons, while there were only 2 such concurrent charges in individuals charged with child molestation (N=111). Individuals charged with sodomy (N=42) accounted for 1 charge of murder, 1 of robbery, and 2 of assault. Our small sample of exhibitionists (N=7) had no concurrent charges of crimes against persons.

Psychiatric Illness

We examined the possibility of an association between types of sexual offenses and psychiatric disorders. Since our sample of defendants referred for psychiatric evaluation is biased toward the finding of psychiatric illness, we felt that any association between mental disorders and deviant sexual behavior should be evident. Table 1 gives a breakdown of psychiatric diagnoses for several groups of offenders. The predominant diagnostic grouping for those charged with rape is personality disorder; antisocial personality was found in 48% of this group. Psychosis (affective disorder, organic brain syndrome, or schizophrenic process) was reported for less than 15% of the defendants charged with rape or attempted rape. Over three-fourths of the rape defendants fell in the categories of personality disorders or no psychiatric illness.

A different picture emerges for those charged with child molestation: personality disorders are not predominant, and only 6% of these defendants were found to be antisocial. The dominant diagnosis is sexual deviant (pedophilia) without other disorder, which was given to 29% of this group (32 of the 34 cases in the "other" category). This group, combined with those categorized as having no psychiatric illness, constitutes over a third of all the child molesters seen. Other categories that contribute heavily to the diagnostic distribution in this group include organic brain syndrome, mental retardation, and schizophrenia, which were found in almost two-fifths of the cohort charged with child molestation. Alcoholism and drug abuse were the predominant secondary diagnoses in both rape and child molestation, constituting one-third of the secondary diagnoses for these two groups of defendants.

We examined the influence of major psychiatric disorders in defendants charged with sexual crimes by looking at the incidence of schizophrenia and affective disorders among defendants charged with such offenses. Police records from the years 1961 through 1973 for all rapists and other sexual offenders (excluding offenses involving commercial vice) were obtained. Unfortunately, child molestation was not kept as a separate category by the police. We then reviewed records of those in this group charged with rape and other sexual offenses who were seen on the Forensic Service between 1961 and 1973 for the presence of either illness. Since the Forensic Service is the only such service in St. Louis and receives more than 90% of its defendants from St. Louis City Courts, we assumed that the defendants with diagnoses of either schizophrenia or affective disorder would be in the group of defendants seen on the Forensic Service. This assumption is supported by the referral of a large proportion of defendants without severe psychiatric disorders, indicating a high index of suspicion of psychiatric illness on the part of the court. This makes it unlikely that the courts would overlook a significant number of defendants with serious psychiatric problems. Further, a study of convicted felons in Missouri found little psychosis in the prison population (4).

Schizophrenia, including cases of schizo-affective disorder, was found in 0.3% of all rapists (8 of 2657 cases) and 0.22% of other sexual offenders (11 of 4793

cases). No affective disorders were found among persons charged with rape and only 0.08% of other sexual offenders received this diagnosis.

The report to the court indicated that out of 104 requests for sanity evaluations in defendants charged with child molestation, 79 were found to be sane, and out of 105 competency evaluations, 86 were considered competent. For those charged with rape, 38 out of 40 evaluated for sanity were found sane, and 40 of 43 evaluated for competency were found competent. These figures indicate that insanity plays almost no role in rape, especially since this sample represents cases in which there is a potential psychiatric illness.

DISCUSSION

The findings we have presented allow us to suggest a typical profile for defendants charged with child molestation and rape. The rapists seem to be males under 30 with histories of antisocial behavior. They might also have a history of violent behavior, and their antisocial tendencies would not, for the most part, be confined to sexual areas. Major mental illness (psychosis, thought disorder, and/or delusions) would be unlikely in these individuals. This profile is comparable to that of the offenders studied by MacDonald (3)—75% of his sample were under 30, the vast majority had committed previous crimes, and 15% had a concurrent charge of robbery. He also found a disproportionate incidence of blacks among his offenders, and 41 of the 67 accused rapists we studied were black. No estimate of concurrent mental illness was given in MacDonald's study, but his impression was that it was very low. McCaldon (5), in a study of 30 convicted rapists, found that half had antisocial personalities. Gebhard and associates (6) estimated that less than 1% of rapists have psychotic illness. Amir (7) also found that young black antisocial males were the largest group among defendants charged with rape.

These data are consistent in suggesting that youth and antisocial tendencies are the most common features of rapists. More interestingly, they suggest that psychosis in no way predisposes an individual to sexual assault. Clinical impressions and data from the St. Louis Forensic Service suggest that the incidence of psychosis in rapists is lower than that among the general population. The myth of the "crazy rapist" seems to apply to the extreme exception, and from our data it could even be suggested that psychosis protects individuals from the possibility of committing rape.

The profile of child molesters suggests no particular age and, most likely, no psychiatric diagnosis other than sexual deviation. These individuals are unlikely to evidence other criminal behavior, and violence is not a feature of their activities. In our sample, mental retardation and organic brain syndromes were not uncommon, and 11% of those charged with child molestation were diagnosed as schizophrenic. Mohr and associates (2), in a study of 68 pedophiles, found a trimodal age distribution and an IQ range only slightly skewed to the lower end of the scale. They also found little violent or other criminal behavior in their sample. The incidence of psychosis was very low in their study and those they reviewed. The relatively high proportions of defendants with mental retardation, organic brain syndromes, and schizophrenia in our study reflect the fact that our subjects had been referred for a psychiatric evaluation, which would be expected to maximize psychopathology in the sample. Again, crude calculations suggest that the incidence of psychosis among pedophiles in general is very low.

The most common secondary diagnosis in both groups of offenders was alcohol or drug abuse. Alcohol, even without alcoholism, plays a major role in these offenses. This was suggested by Rada (8), who found that 50% of convicted rapists had used alcohol before committing their offense. The role of alcohol and secobarbital in violent assaults was also emphasized in a recent report by Tinklenberg and associates (9).

CONCLUSIONS

In summary, we found two distinct populations among sexual offenders referred for a psychiatric evaluation. The first, young and antisocial with a tendency toward violent crime, was involved in rape. The second, of varying ages with no marked antisocial tendency but some chance of suffering from organic brain syndromes, mental retardation, or schizophrenia, was pedophiliac. Psychosis does not appear to be associated with either of these sexual offenses.

Peer Review of Prescribing Patterns in a CMHC

BY HERBERT DIAMOND, M.D., RICHARD TISLOW, M.D., THOBURN SNYDER, JR., M.D., AND KARL RICKELS, M.D.

Monitoring the prescribing patterns of psychiatrists is a challenging and now necessary professional responsibility. The authors describe a peer review and feedback system in a decentralized CMHC, linked to continuing education in psychopharmacology, that made staff psychiatrists familiar with the state of the art and accountable for practice within its guidelines. Data are presented that confirm shifts from polypharmacy toward more appropriate use of psychotropic medications.

THE MODERN ERA of psychopharmacology has evolved over the last two decades. In this relatively short period of time a new armamentarium of effective psychoactive agents has been developed, studied, and introduced into clinical psychiatric practice. For the first time psychiatric clinicians have available some uniquely therapeutic medications. Out of a massive clinical experience a number of authors have identified some ubiquitous problems in the use of these medications that point to new directions prescription practices must take in order to dovetail more appropriately with the state of the art (1–3).

The major problems highlighted in the literature include drug overuse and polypharmacy—combining multiple antipsychotic or antidepressant agents, excessive pairing of antipsychotic with antidepressant agents, and overuse of antiparkinson drugs. DiMascio (4) examined prescription practices in hospital settings and discussed the "folly of polypharmacy," as well as many instances of inappropriate use of individual drugs. Merlis and associates (5) also studied polypharmacy and concluded that it was not an adequate form of treatment. More specifically, a number of authors (6–9) have investigated the use of antiparkinson with antipsychotic agents and have presented data indicating that 70% to 90% of all patients so treated were given unnecessary prophylactic antiparkinson agents to reduce or eliminate extrapyramidal-like side effects of the primary antipsychotic medication.

In the course of a regular review of prescriptions written by staff psychiatrists in a large urban community mental health center (CMHC), one of us (H.D.) observed the perpetuation of practices that were increasingly being questioned by leading clinical psychopharmacologists. Monitoring of the prescribing patterns of our dispersed staff of psychiatrists not only met some needs of managerial accountability but also aimed at an optimum and consistent use of psychotropic medications throughout the center's service delivery system.

This was an ambitious undertaking since the West Philadelphia Community Mental Health Consortium, Inc., is a complex, decentralized CMHC that has developed a comprehensive system of mental health/mental retardation (MH/MR) services now consisting of 18 programs in 29 facilities. The Consortium represents its community by coordinating the activities of a local planning agency and the major health and educational institutions in the catchment area. It has brought together 11 institutions and their communities in a collaborative MH/MR venture in southwest Philadelphia. Four general physicians and 16 psychiatrists have responsibility for chemotherapy in the outpatient network of services that has been developed around a group of 7 neighborhood clinics, a partial hospitalization program, and components of an aftercare service.

The goal of developing prescription practices throughout the system that were consistent with the state of the art led to the development of an intramural review of prescriptions that had been issued free of charge by the Consortium's central pharmacy in one member hospital. Prescriptions for patients on public assistance are filled in Pennsylvania by local pharmacists, who are then reimbursed by the Department of Welfare. However, because this information had not yet been computerized, these medical assistance prescriptions were not available to the project.

Two years ago, the monthly prescription summaries began to be reviewed regularly in a conference setting by the medical director and psychiatric staff for rele-

Presented at the annual meeting of the American Psychiatric Association, Anaheim, Calif., May 5–9, 1975.

Box 8076, Philadelphia, Pa. 19101. Dr. Rickels is also Director of Psychopharmacology, Philadelphia General Hospital. The authors are also with the University of Pennsylvania School of Medicine, where Dr. Diamond is Associate Professor of Psychiatry and Associate Director of the Division of Community Psychiatry, Drs. Tislow and Snyder are Associates in Psychiatry, and Dr. Rickels is Professor of Psychiatry and Pharmacology.

The authors wish to thank Ms. Lenore J. Diamond for tabulation of data and Ms. June Walker for preparation of the manuscript.

vance to diagnosis, treatment of target symptoms, and the current literature. The conference became an ongoing seminar in psychopharmacology.

Since monitoring the professional performance of psychiatric colleagues presented a delicate although necessary responsibility, great care was taken to explain the purposes of the review, i.e., to improve prescribing skills, upgrade care, reduce costs where possible, and enhance continuing education. The last goal was particularly emphasized and consistently reinforced, and the psychiatric group coalesced around this important educational experience. Many in the group promptly applied their new knowledge to their part-time private practices with good results; this in turn reinforced enthusiastic participation in the review process in the CMHC. Although we had anticipated considerable resistance to this unfamiliar and possibly threatening professional exposure, we found that initial reservations readily gave way to a spirited acceptance of the opportunity for continuing education.

Since biweekly meetings could not possibly cover 450–650 monthly prescriptions, we decided to establish a medication review committee. By group consensus, a committee of 4 senior clinicians was mandated to review all prescriptions on a continuing basis and to question the individual practitioners about their rationale for polypharmacy, duplication of antipsychotic or antidepressant agents, or prescription of long-term antiparkinson medication. A monthly feedback mechanism was established in the form of a nonthreatening statement to each physician identifying the questionable medication regimen and requesting a response to the issues raised. Subsequently, these staff responses were returned to the committee, which then periodically reviewed them with the entire group of physicians in the regular seminar led by our consultant psychopharmacologist (K.R.).

METHOD

In order to study the impact of our peer review system on psychotropic medication prescription patterns, comparisons were made of two 2-month periods, one in 1973 and one in 1974. We compared the daily medication regimens prescribed in April and May of 1973 with those in October and November of 1974; these two periods, 18 months apart, adequately covered the implementation of the review and seminar process through its initial phase. We simply counted how many medications were prescribed once, twice, three times, or four times a day, omitting all prescriptions for antiepileptics and for minor tranquilizers (such as diazepam) that could have been given appropriately several times a day and therefore would not have been expected to show a decreased daily use. We also excluded all hypnotics since they are usually given once daily at bedtime, and their use was therefore not expected to change.

In a second comparison study, we counted the number of different drugs prescribed per patient and compared the results in April and May of 1973 with both April and May of 1974 and October and November of 1974. Because of staff turnover a number of physicians on the staff in 1973 were only available for the April and May comparison in 1974; we therefore chose to study only the prescriptions of those physicians who were available in April and May of 1973 and 1974. Chi-square analyses were then applied to the collected data.

RESULTS

Table 1 summarizes daily medication regimens for 1973 and 1974. Since the 1973 daily dosage schedules were not routinely recorded on the early prescription summaries or readily available, many original clinical records had to be reviewed. The differences in sample size between 1973 and 1974 can be attributed primarily to an increased patient caseload in 1974 and also to some 1973 data that were not readily available. As can be seen in the table, there was a decrease in the daily frequency of drug administration, with significantly more patients prescribed once-a-day medication compared with divided-dose regimens. The shift is highly significant when compared with the former twice, three times, or four times a day dosage patterns ($p<.001$).

Table 2 summarizes the multiple-drug study and presents the number of drugs prescribed to individual patients during two comparable periods. As can be seen, a significant decrease in polypharmacy had occurred—more patients in 1974 than in 1973 were given only 1 or at the most 2 medications.

When we examined the use of antiparkinson drugs during the same two periods, we found that of 205 patients in 1973, 138 (67%) were treated with a combination of antipsychotic and antiparkinson agents, while in 1974 only 103 of 195 patients (53%) were so treated. These data indicate a significant decrease in the use of antiparkinson agents as a result of the peer review ($\chi^2=8.17$, df=1, $p<.01$).

In a separate recently reported study from the seminar group (10), 39 of 49 outpatients (79%) who had received a phenothiazine plus benztropine mesylate (Co-

gentin) for at least 3 months were able to give up benztropine mesylate with minimum or no sequelae, a result consistent with other reports in the literature.

Finally, we compared multiple versus single antipsychotic drugs prescribed in the same treatment periods and found less polypharmacy with antipsychotic drugs in 1974 than in 1973. In 1973, 134 of 205 patients (65%) received only one antipsychotic agent, while in 1974, 152 of 195 patients (78%) received only one antipsychotic agent (χ^2=7.16, df=1, p<.01).

DISCUSSION

This intramural peer review at the West Philadelphia Consortium has had two major spin-offs. First, our psychiatrists have been trained to be more effective chemotherapists. Each staff psychiatrist is now familiar with the state of the art and is more responsive to its guidelines. As a result, there has been a concurrent improvement in this dimension of the quality of psychiatric care in the agency. However, our data also clearly indicate that the optimum use of psychotropic medications throughout the center's outpatient service delivery system still remains a goal that will require active peer review and continuing education.

Unfortunately, the chemotherapy of our hospitalized patients still appears to be rooted in polypharmacy; this carries over and introduces problems into outpatient medication maintenance. In addition, newly recruited clinicians, even though they may be experienced, seem to practice polypharmacy and to lack an adequate appreciation of the risks of nondiagnosis, reduced phenothiazine efficacy, toxic psychosis, and tardive dyskinesia.

A second major spin-off has been the enhanced development of additional components of a more comprehensive peer review mechanism in the decentralized outpatient programs of the center. These new activities now include review committees on continuity and quality of care. This experience in monitoring prescribing patterns has thoroughly sensitized us to the review requirements of recent legislation authorizing the development of Professional Standards Review Organizations (PSROs) (11) and Health Maintenance Organizations (HMOs) (12). There is no doubt that the new standards for CMHCs currently being developed by the Joint Commission on Accreditation of Hospitals as well as the standards set for a future national health insurance program will demand efficient peer review systems to monitor staff utilization, cost-effectiveness, and quality of care. These currents in clinical and community psychiatry clearly signal increasing third-party review of our service delivery systems, substantiation of the effectiveness of our interventions, and justification of our fees. Medication review is an essential beam in a basic framework for such new accountability.

Use of the Problem-Oriented Medical Record in Psychiatry: A Survey of University-Based Residency Training Programs

BY EDWARD H. LISTON, M.D.

A survey of university-based psychiatric residency training programs revealed that nearly one-half of them use the problem-oriented medical record (POMR) and that conversion to this system appears to be growing rapidly. Experiences with the method have in general been positive. The author identifies factors associated with successful operation of the POMR and suggests that an integrated, hospital-wide adoption of the system may be crucial.

IT HAS BEEN several years since Weed (1–3) first advocated the abandonment of the traditional source-oriented medical record system and the adoption of a problem-oriented medical record (POMR) system. While most of the literature on the POMR has addressed the medical-surgical fields, there has been a recent growth in reports of the application of this method to psychiatry (4–16). However, the extent to which the system is actually used, the ease or difficulty of implementing it, and its success or failure in psychiatry are unknown on a nationwide basis. Moreover, there does not seem to be any indication in the literature of the degree to which residents in psychiatry are being taught or exposed to the POMR system. This paper is a report of an attempt to answer these questions and to provide an overview of the POMR in American psychiatric training programs.

METHOD

In November 1974 a questionnaire designed to obtain data on the use of the POMR was sent to the 95 U.S. university medical centers and schools of medicine that have psychiatric residency programs. The choice of this restricted sample was dictated by the large number of training programs in psychiatry throughout the country and by the advantages of uniformity for purposes of comparison. In addition, the sample selection was predicated on the assumption that experiences in university centers may influence subsequent general application of the POMR to psychiatric education and practice. Respondents from programs that used affiliated hospitals for training were requested to answer the questionnaire as it applied to that facility that was considered to be their primary teaching hospital. The referent POMR system model was one which included the interaction of a data-base, problem-list, plan for each problem, and progress notes organized by problem.

Dr. Liston is Assistant Professor, Department of Psychiatry, and Chief, Adult Inpatient Services, Neuropsychiatric Institute, School of Medicine, University of California, Los Angeles 90024.

RESULTS

Of the 95 institutions surveyed, 59 (62%) responded within four months. Two respondents did not provide sufficient information for analysis and were excluded from tabulation. Of the remaining 57 programs, 24 (42%) used the POMR system and 33 (58%) did not. Unless otherwise noted, statistical comparisons are based on these two proportions. (A telephone survey of 34 of the nonrespondents revealed that 9 used the POMR and 25 did not. The experiences and opinions of both of these groups in general paralleled those noted in the following sections.)

PROGRAMS USING THE POMR

The earliest introduction of the POMR among the 24 training centers using the system was in 1970, but nearly three-fourths of the centers did not adopt the system until 1973 or 1974. The POMR was used throughout the range of clinical services, most frequently on adult inpatient units; and it was used by all professional disciplines in more than 75% of the programs. Similarly, most of the training centers reported wide application of the system to components of the medical record, especially progress notes, and three-quarters of them employed a master problem list. Twenty (83%) of the psychiatric programs reported concurrent use of the POMR on affiliated medical-surgical services.

In addition to on-the-job training, implementation of the system was assisted in almost all programs by a variety of staff education techniques including seminars, lectures, workshops, films, and instruction manuals. While there was general uniformity in the use of these devices, none was demonstrably more effective than any other. However, there is a suggestion that lectures and seminars were more conducive to successful implementation than other techniques.

Factors Associated with Success of the System

Twenty-one (88%) of the residency programs reported successful operation of the POMR system. Only 1 institution reported that the method failed to operate at all effectively, while 2 others stated that it had been somewhat unsuccessful. Several factors were associated with the operational success of the system (see table 1).

None of the differences between the 2 groups with good and poor success reached statistical significance for any of the associated factors, due in part to the technical problem of very small numbers in the poor success group. However, the marked difference noted in the use of the POMR by affiliated medical-surgical specialties approached statistical significance (p=.06, Fisher exact probability test), suggesting that an integrated, hospital-wide adoption of the system may be necessary for successful operation in psychiatric programs. This observation is supported by a report (17) that the absence of uniform use of the POMR among clinical departments constitutes a major problem in teaching this system to medical students. The data indicate that successful operation of the POMR is positively correlated with both comprehensive application of the system and the requirement that it be used.

Length of operation of the POMR system in a program was also associated with successful experience. All 3 of the relatively unsuccessful programs were less than a year old, compared with only 4 of the 21 successful ones. Comparison of these two proportions by the Fisher exact probability test revealed that their difference was significant (p=.02). This finding may be an indication of the growing pains that are to be expected whenever such changes in established procedures are undertaken. In addition, it supports comments by respondents to the effect that as their experience with the POMR grew, critical evaluation and resistance progressively lessened.

TABLE 1
Factors Associated with Operational Success of the POMR System in 24 Programs

Factor	Percent of Programs Reporting Operational Success	
	Good (N=21)	Poor (N=3)
Use of POMR by affiliated medical-surgical specialties	90	33
Use of a master problem list	81	33
Use of POMR in three or more sections of the medical record	76	33
Use of POMR required on one or more clinical services	71	33
Use of POMR by one or more clinical disciplines required	71	33

Services			
Required	3	0	p=.05
Optional	0	4	
Disciplines			
Required	18	0	p=.001
Optional	0	3	
Medical record			
Required	9	0	p=.01
Optional	0	3	

* Fisher exact probability test.

Resistance

Predictably, resistance (i.e., noncompliance and opposition) to the implementation and operation of the POMR system was higher in institutions reporting poor success than in those centers whose experiences were more positive. Two training centers reported negligible resistance and 2 indicated marked resistance to implementation of the new system. Examination of their questionnaires revealed that low resistance was associated with required use of the method and, conversely, high resistance with the programs that permitted or encouraged but did not require its use. This finding was true for the use of the POMR in all clinical areas, especially in the professional disciplines (see table 2). The importance of mandatory use of the method is further underscored by the assertion of one respondent that resistance to the system was effectively avoided through "implementation by dictum" combined with instructional discussion groups. In this school, implementation of the POMR was very smooth and operation of the system has been very successful.

Resistance to the POMR method by nonmedical disciplines generally tended to be low, although moderate resistance was reported by 40% of the social workers and marked resistance by 15% of the clinical psychologists. However, the greatest opposition was found among the medical faculties of the institutions; resistance lessened with each successively lower step in the level of medical training (see table 3). Chi-square analysis of this pattern shows it to be highly significant (p=.01).

It is, of course, most likely that this finding reflects the greater general conservatism and rigidity that tend to accompany advancing experience and the fact that license for dissent and opposition tends to be restricted at the lower levels of the medical hierarchy. This observation about the POMR has been noted by others (16–19), and it is apparently a critical consideration in the successful implementation and use of the method. That is, several of the respondents emphasized that commitment to the new system throughout all clin-

TABLE 3
Level of Medical Training and Resistance to the POMR System

Training Level	N	Programs Reporting Resistance*			
		Moderate–Marked		None–Mild	
		N	Percent	N	Percent
Medical staff	22	13	59	9	41
Fellows	8	3	38	5	62
Residents	22	7	32	15	68
Medical students	16	1	6	15	94

* There was a pattern of significantly more resistance as the level of medical training increased ($\chi^2 = 11.34$, df=3, p=.01).

ical disciplines is necessary for its optimal operation and that leadership and direction must derive from the highest levels of institutional authority if smooth transition from the source-oriented to the problem-oriented system is to occur.

Comment

Approximately 90% of the training programs that were using the POMR believed that the system is adaptable to and useful in psychiatry and that its advantages outweigh its drawbacks. In addition, while 32% of the respondents reasoned that the POMR has somewhat better applicability to other specialties, 82% advocated widespread use of the system in psychiatry.

PROGRAMS NOT USING THE POMR

Of the 33 training programs that were not using the POMR system, approximately 80% reported that their faculty members generally were familiar with the problem-oriented concept. Plans to implement the POMR in these schools were mixed; 7 intended to adopt the system and 7 did not, while the remaining 19 were uncertain. (One institution reported using the POMR for a three-month period and then discontinuing it because of its rejection by the hospital's medical records committee.) Many of these programs expressed uncertainty about the usefulness of the POMR in psychiatry, and nearly one-fourth of the respondents were not sure whether the system has any value in medicine in general. However, only 3 schools asserted that the method is of no value whatever in psychiatry.

The respondents' remarks ranged from enthusiastic support for the POMR in psychiatry to denial of its usefulness at all; some respondents took a "wait-and-see" position. A common criticism of the system was that it is less relevant or applicable to psychodynamic and analytically oriented approaches than to behavioral and psychobiological frameworks. One respondent felt that the system is inherently excellent but that the disdainful attitude by physicians toward medical record-keeping must be counteracted in order for the POMR to work.

DISCUSSION

More than half of the psychiatric training programs that responded to this survey were using or had plans to adopt the POMR system and, from the reported dates of implementation, there apears to be a rapidly growing conversion to this method of documenting patient care. Furthermore, experience with the POMR in these psychiatric residency programs has been, on the whole, quite successful, notwithstanding its recent invention and its dissimilarity to the more familiar and traditional source-oriented medical record system.

In addition, the survey results substantiate the observations of others (16–19) that resistance to conversion to the POMR is found principally at the upper levels of the medical hierarchy and that opposition to the system can be avoided or reduced by appropriate leadership and planning and by implementation through means of official policy, preferably on a multidepartmental basis. These observations clearly do not lend support to the notion that the POMR system has little or no applicability to psychiatry; indeed, it is apparent that quite the opposite is true.

The survey methodology was not comprehensive, and many additional important questions remain unanswered. For example, it would be instructive to have learned whether training centers of diverse theoretical persuasions differ in their opinions of and experiences with the POMR system. Furthermore, as one respondent observed, there was no provision for assessing the methods and extent of audit and correctional feedback, which have been seen as crucial to the survival of the problem-oriented system (10). Nonetheless, this survey indicates that use of the problem-oriented medical record system in psychiatry is not merely a transitory and fashionable phenomenon. Moreover, the fact that this new method is now being taught in approximately 80% of all U.S. medical schools (17) forecasts a progressive extension of the POMR system throughout all levels of American medicine, which will continue to embrace and influence psychiatric education and practice.

Low Urinary Dopamine and Prediction of Phenothiazine-Induced Parkinsonism: A Preliminary Report

BY THOMAS J. CROWLEY, M.D., CHARLES O. RUTLEDGE, PH.D., MARGARET M. HOEHN, M.D., MARY ANN STALLINGS, R.N., M.S., AND SEYMOUR SUNDELL, M.D.

Psychiatric patients who excreted larger amounts of urinary free dopamine before treatment were significantly more likely than patients excreting smaller amounts to develop parkinsonian side effects during moderate-dose trifluoperazine therapy. If this finding is replicated, urinary free dopamine determinations could prove valuable in indicating which patients should receive those antipsychotic drugs least likely to produce extrapyramidal side effects.

MOST ANTIPSYCHOTIC (neuroleptic) drugs, including the phenothiazines, produce extrapyramidal side effects, the most common of which is the parkinsonian syndrome of hypokinesia, rigidity, and tremor. The incidence of these parkinsonian reactions varies with the dose and type of drug and perhaps with the patient's age and duration of treatment (1, 2).

In idiopathic Parkinson's disease the nigrostriatal pathway degenerates, and dopamine, the proposed neurotransmitter in this pathway, is then present in amounts insufficient to inhibit neurons originating in the striatum (3–5). The severity of akinesia in idiopathic Parkinson's disease directly correlates with the deficiency of brain dopamine (5). Compared with normal controls, parkinsonian patients also excrete reduced levels of dopamine in the urine (6–8). Urinary levels of free (unconjugated) dopamine appear to correlate negatively with the presence of parkinsonian akinesia (8) and, according to our observations, with its severity. Thus considerable evidence suggests that in Parkinson's disease the levels of free dopamine in the urine may at least reflect differences in brain dopamine metabolism, even though much of this free dopamine may originate peripherally.

Parkinsonism induced by antipsychotic drugs is thought to result from drug blockade of dopamine receptors, rendering striatal neurons less responsive to dopamine inhibition (9, 10). These drugs may also reduce the release of dopamine within the basal ganglia (11). We hypothesized that those psychiatric patients with low urinary dopamine levels before treatment would be at greatest risk for developing parkinsonian side effects from antipsychotic drugs; this article reports a preliminary test of that hypothesis.

When this work was done, the authors were with the University of Colorado Medical Center, 4200 East Ninth Ave., Denver, Colo. 80220, where Dr. Crowley is Associate Professor of Psychiatry, Dr. Rutledge was Associate Professor of Pharmacology, Dr. Hoehn is Assistant Professor of Neurology, Ms. Stallings is Research Nurse in Psychiatry, and Dr. Sundell is Resident in Psychiatry. Dr. Rutledge is now Professor and Chairman, Department of Pharmacology and Toxicology, School of Pharmacy, University of Kansas, Lawrence, Kans.

This work was supported in part by National Institutes of Health grant NS-09199 from the National Institute of Neurological Diseases and Stroke.

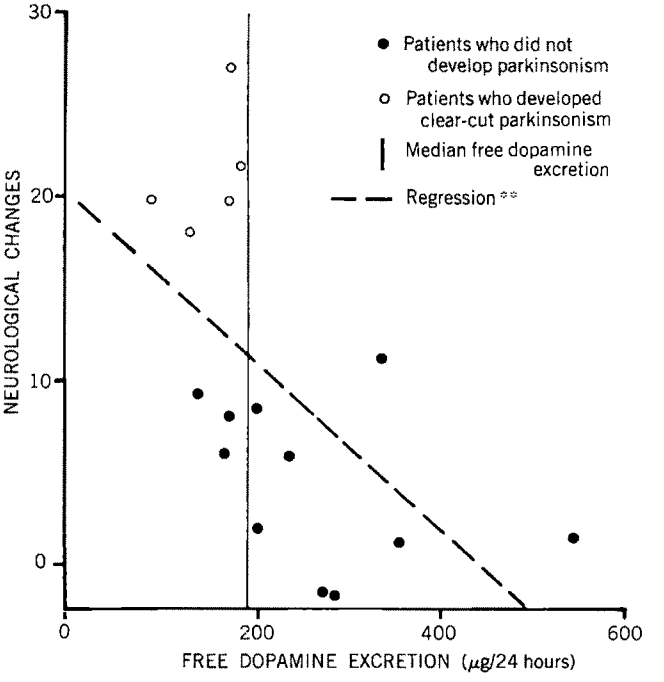
The authors appreciate the technical biochemical assistance of Ms. Amy Zirrolli and Ms. Diann Miller, the statistical advice of Donald Stilson, Ph.D., and the cooperation of the physicians and nurses who treated the patients.

METHOD

Criteria for admitting patients to the study were 1) voluntary admission for acute psychiatric treatment to the Colorado Psychiatric Hospital or the Denver Veterans Administration Hospital, 2) a clinician's decision that an antipsychotic drug was needed but that the patient's degree of agitation permitted deferral of treatment for 2 days during initial evaluation, 3) no use of antipsychotic or antidepressant medication by the patient for at least 11 days before entering the study, 4) no recent heavy use of alcohol or other drugs of abuse, and 5) the patient's informed consent to the study procedures.

The subjects were 8 men and 8 women ranging in age from 20 to 57 years (mean=31). Diagnoses according to *DSM-II* (12) criteria were schizophrenia, N=14; psychotic organic brain syndrome, N=1; and obsessive-compulsive personality disorder, N=1. This was the first psychiatric admission for 7 patients and the second or third for 6; 3 patients had had four or more admissions.

The severity of parkinsonian signs was scored from 0 to 100 points on a standardized neurological examination (13) before antipsychotic drug administration and then about 3 times a week for 2 weeks or until unmistakable parkinsonian signs developed.



Pretreatment 24-hour urine samples were collected once (1 patient), twice (14 patients), or three times (1 patient) and were analyzed in duplicate for free and conjugated dopamine by techniques described previously (14). The means of the daily values were used to calculate each patient's dopamine excretion rate. The biochemical technicians and neurological examiners were unaware of one another's data.

Patients received oral trifluoperazine HCl (Stelazine) in a low-dose schedule increasing from 0 at a rate of 4 mg/day (15 patients) or in a high-dose schedule increasing by 8 mg/day (1 patient); the high-dose schedule was used when the treating clinician decided that the patient's condition warranted a rapid increase in dose. Daily increases stopped when the dose reached 40 mg/day or when clinical improvement or side effects occurred. The treating physicians could modify the schedules when this was clinically warranted. No antiparkinsonian drugs were administered during the study. Correlations were analyzed by the Pearson product-moment method.

RESULTS

In figure 1 the difference between the predrug neurological score and the highest (most pathological) drug-period score for each patient is plotted against the predrug excretion of free dopamine. All 5 of the patients who developed obvious parkinsonism changed by 18 points or more. One patient who changed by 27 points had severe parkinsonian signs. The other 11 patients changed by less than 11 points and did not develop parkinsonism; their extrapyramidal signs were transient, less severe, and less definite.

FIGURE 1
Pretreatment Free Dopamine Excretion and Neurological Change with Trifluoperazine Therapy*

*Higher scores indicate the development of more marked extrapyramidal signs.
**$Y=a+b_{xy}X$.

The mean 24-hour free dopamine excretion was 225.4 μg (SE_M=28) and the median was 190. The 5 patients who developed parkinsonism were among the 8 patients who excreted less than 190 μg/24 hours of free dopamine. None of the 8 patients who excreted more than that amount developed the syndrome. Parkinsonism was significantly more common among the patients excreting less than 190 μg/24 hours ($p<.025$, Fisher's exact test). There was also a significant negative correlation between the change in neurological score and the pretreatment free dopamine excretion ($r=-.56$, $p<.025$).

Changes in neurological scores did not correlate significantly with total (free plus conjugated) dopamine excretion, age, sex, or the patient's trifluoperazine dosage on the day of his/her maximum neurological score during the drug period (mean=.39 mg/kg, SE_M=.04). Neurological change was also not significantly correlated with the total dose received by each patient over the 2 weeks of the study (mean=4.43 mg/kg, SE_M=.26) or with the maximum daily dose achieved by each patient (mean=.47 mg/kg, SE_M=.03). It was not possible to determine accurately the previous phenothiazine exposure of these patients; we used the number of previous hospitalizations as a rough indicator of previous treatment and found no significant correlation with either neurological change or predrug free dopa-

mine excretion. Furthermore, free dopamine excretion did not correlate significantly with the number of days the patient had received the hospital diet before the first urine collection.

An analysis of variance (15) comparing the dopamine excretion rates among patients, the rates between successive days for each patient, and duplicate assays on each daily sample revealed substantial interpatient differences ($p<.005$). Differences between days approached significance ($.05<p<.10$). Differences between duplicate assays were not significant. Moreover, there was no significant systematic change in the measured dopamine levels across the months in which the determinations were performed (16).

DISCUSSION

Urinary dopamine probably originates from dietary sources (7, 17) and from peripheral organs (8), as well as from the brain. In fact, the central nervous system (CNS) contribution to urinary dopamine may be relatively small. In the rat an 80% decrement in brain dopamine results in a nonsignificant decline (less than 15%) in urinary dopamine (18). Whatever its source, the well-established reduction in urinary dopamine excretion among parkinsonian patients (6, 8), which is observed under either special or ad lib diets (7), suggests that dopamine excretion in some way mirrors CNS dopamine metabolism. Barbeau (8) argued that the pathology of parkinsonism is not limited to the nigrostriatal pathway and that this is a "systemic" disease with widespread abnormalities of dopamine metabolism. This view is supported by recent evidence that patients with Parkinson's disease show impaired uptake of dopamine in blood platelets (19). The concept may be further supported by our observation that psychiatric patients excreting less than 190 μg/24 hours of free dopamine were significantly more likely than other patients to develop extrapyramidal disorders during subsequent treatment with trifluoperazine.

Reported levels of dopamine excretion vary among different subjects and different laboratories (6–8). Our range was well within limits reported elsewhere, and we showed statistically reliable interpatient differences in dopamine excretion. These differences correlated with, and thus predicted, the subsequent development of parkinsonian signs.

Since dopamine excretion may vary with diet, it is possible that by chance alone those patients with the greatest tendency to develop phenothiazine-induced parkinsonism also happened to be those on diets relatively poor in catecholamines, producing a spurious relationship between dopamine excretion and extrapyramidal signs. Similarly, phenothiazine absorption after oral ingestion could vary and, again by chance alone, those patients who excreted less dopamine also could have been those who happened to absorb more trifluoperazine, resulting in higher blood levels and an increased risk of extrapyramidal symptoms. We cannot rule out such chance occurrences, but their probability is less than 3 in 100 according to our statistical analyses.

Might diagnostic or treatment differences have produced the differences in neurological change? Two patients were not schizophrenic. The patient diagnosed as an obsessive-compulsive personality excreted low amounts of dopamine and became parkinsonian; the patient with an organic brain syndrome excreted over 300 μg/24 hours and did not become parkinsonian. Thus, in terms of dopamine and neurological change, these two nonschizophrenic patients responded similarly to the rest of the group. The treating clinicians decided to increase the dose of 1 patient more rapidly than the others, using the "high-dose" schedule. This patient had the lowest dopamine excretion and was among the 5 patients who became clearly parkinsonian. Thus it is possible that dose differences contributed to the final result in this case. However, for the group of patients, the neurological change did not correlate significantly with the total dose received during the study, the highest daily dose received by each patient, the dose received on the day of each patient's highest neurological score, or with a rough estimate of past drug exposure. Furthermore, neither age nor sex was correlated with drug-induced parkinsonism in this sample, although these factors appear to be important in older, more chronic inpatient populations (1, 2). Only pretreatment free dopamine excretion correlated with parkinsonian changes.

If replicated, the correlation we have reported may be of value in indicating which patients should receive those antipsychotic drugs least likely to induce parkinsonism. Its eventual application, however, would depend on the establishment of standard excretion values of dopamine and its metabolites for populations differing in age, prior and recent drug exposure, and planned therapeutic dose. Higher doses, for example, may increase the incidence of extrapyramidal disorders (20); the critical dopamine level for developing parkinsonism might have been other than 190 μg/24 hours if somewhat higher doses or a more potent drug such as fluphenazine (Prolixin) had been administered.

Sex Bias in Psychotherapy: A Failure to Confirm

BY STEPHEN I. ABRAMOWITZ, PH.D., HOWARD B. ROBACK, PH.D., JOSEPH M. SCHWARTZ, M.A., AMY YASUNA, CHRISTINE V. ABRAMOWITZ, PH.D., AND BEVERLY GOMES, M.A.

The authors examined the questions of sex-related countertransference and bias in psychotherapy by asking 65 male and 57 female experienced group therapists for clinical reactions to case materials of a bogus outpatient who was designated either male or female. They found that varying the patient's gender produced only small differences in the therapists' responses, and conclude that sex-related countertransference problems may not be as prevalent as had been previously thought.

THE REEMERGENCE of the women's rights movement has intensified professional concern about the potential for covert acts of sex discrimination perpetrated under the banner of mental health care (1). The cumulative weight of experimental and archival research with diverse practitioner and clinical populations has not succeeded in allaying this concern (2, 3).

A simple but clever study by Masling and Harris (4) yielded evidence that the clinical situation can be a source of voyeuristic need gratification for the professional. Male clinical psychology graduate students were found to administer more sexual-romantic cards from the Thematic Apperception Test (TAT) to female than to male examinees, and to extend testing sessions with women by presenting more cards to them. Female trainees were apparently unaffected by the examinee's sex. In a recent clinical analogue, clinicians rated psychological adjustment using the case material of college students identified as male or female and as po-

Drs. Stephen and Christine Abramowitz are Assistant Professors of Psychology, Department of Psychiatry, Sacramento Medical Center, University of California, Davis, Sacramento, Calif. The authors wish to thank Ms. Barbara Miller for her help with data collection.

litically liberal or conservative. The liberal woman received the most censorious evaluations, especially when the clinicians were relatively conservative (5).

Results from two investigations (6, 7) tentatively implicate the practitioner's sex-role attitudes as a source of countertransference in case selection and termination. In the first study, 11 male counselors at a university counseling center carried case loads having an approximately equal sex distribution, whereas 4 female counselors' case loads included a disproportionate number of women. Cultural bias against placement of women in dominant social roles over men was offered as an explanation (6). Similar results, as well as more subtle manifestations of sex-role-related countertransference, were subsequently obtained at both a psychiatric and a psychological training facility (7). Women were seen for more sessions than men when the psychotherapy trainee was a man. In addition, female therapists at the psychiatric clinic saw proportionately fewer single or divorced (sexually unattached) patients than did male therapists, and the 2 single female therapists saw a smaller percentage of sexually unattached men than the 1 married female therapist. We surmised (7) that conventional sex-role expectations may prime male therapists to prolong, and their female colleagues to avoid, treatment situations likely to arouse sexual curiosity.

Evidence that sex-role-linked countertransference influences the treatment careers of group therapy patients is limited to a single, tangential finding (8). One female and 8 male psychiatrically trained clinicians performed intake interviews and sometimes conducted the treatment of patients at a university-affiliated health center. The interviewers referred proportionately more female than male applicants to individual than to group psychotherapy, reinforcing the notion of voyeuristic need gratification.

The present study was undertaken to determine if the notion of sex-role countertransference could be generalized to conventionally trained, experienced group therapists. To ensure greater sample representativeness than is usual in studies of political bias, a clinical analogue method adapted from Strupp (9) was used. Male and female practitioners were presented with written case material of a bogus group therapy outpatient designated as male or female. They were then asked to indicate their clinical reactions to this person and to complete a traditional moralism questionnaire.

METHOD

Subjects

Prospective subjects comprised a sex-stratified random sample of 600 members of the American Group Psychotherapy Association (AGPA). The AGPA is a multidisciplinary professional organization whose membership requirements include extensive supervised group therapy experience. Usable data were returned by 65 male and 57 female therapists (slightly over 20% of the target population). Demographic information was obtained from the AGPA directory (10) and from the respondents.

Of the research participants, 53% described themselves as psychodynamically oriented, 21% expressed a preference for a client-centered or Gestalt philosophy, and only 2% favored a behavioral model. An eclectic approach was espoused by 24% of the sample. An overwhelming proportion of the respondents had undergone either analysis or other uncovering therapy, and most had been group therapists for more than 10 years. Comparison of 40 respondents (20 men and 20 women, randomly selected) with the same number of similarly selected nonrespondents revealed no significant differences with regard to highest scholastic degree (a possible index of professional commitment) and membership in one of the affiliate societies of the AGPA. These sampling data suggest that the research participants were roughly representative of those originally surveyed.

Instruments

Six items tapped the therapist's clinical impressions and degree of liking of the stimulus patient. Questions were counterbalanced, and all response continua were 4-point Likert scales. Subjects were also presented with a list of 19 therapist reactions adapted from the Wile Group Therapy Questionnaire (11). They rank-ordered 3 responses that they would have been most likely to use in the therapy incident involving the bogus patient. The 19 response alternatives represented a broad range of individual- and group-directed categories, from supportive and reassuring to confrontative and interpretive (see appendix 1). First-, second-, and third-ranked choices were scored 3, 2, and 1, respectively. The 12-item, fully counterbalanced, 7-point Likert traditional moralism scale (12) was used to measure traditionalism of social values. Although reliability (coefficient alpha=.58) and discriminability (SD=8.1) were somewhat less robust than reported by the scale's developers (12), the levels obtained compared favorably with those generated by the same and similar instruments used in other surveys of professional samples. Respondents whose raw traditional moralism scores fell above the median were designated as relatively traditional, and those whose scores fell below it as relatively nontraditional.

Procedure

A detailed clinical profile of a group therapy outpatient, including information about family background, employment history, marital adjustment, presenting problems, and psychological test results, was prepared. Sexual performance conflicts and hostile-dependent dynamics were prominent. The case protocol concluded with a description of a representative therapy incident, in which the patient was unusually silent for the first part of a meeting and then began to cry.

The clinical profile was designated as belonging to a man or a woman by systematic reversal of pronoun

gender. The male- or female-identified case materials were mailed with the related response sheets to prospective subjects, who were led to believe that the object of the study was to compile normative data on group therapists' clinical opinions. A sealed debriefing letter that was not to be opened until completion of the simulated clinical tasks was also included.

RESULTS

Data were examined and analyses of variance were performed according to the two-level factors of therapist sex, therapist values, and patient sex. Approximately one-half of the therapist judgment and response dimensions did not produce any differences beyond the .10 level: determinations of social adjustment, mental disturbance, and attraction, and response preferences for silence, group-directed, reassurance-approval, structure, attack, member feeling, leader experience, personal life, past and parents, and nonverbal.

Differences according to therapist sex were found with regard to expressed empathy for the patient ($p<.05$) and the therapeutic strategies of group dynamics question ($p<.05$), psychodynamic interpretation ($p<.05$), behavior change ($p<.05$), clarification-confrontation ($p<.05$), and subtle guidance ($p<.10$). In every instance except clarification-confrontation, female therapists were associated with a higher level of the particular attribute.

Four clinical decisions were related to therapist values. Less traditional respondents were more lenient judges of emotional maturity ($p<.05$) and tended toward more deployment of clarification-confrontation ($p<.10$); more traditional respondents were more partial to behavior change ($p<.05$) and slightly more partial to subtle guidance ($p<.10$). Reliance on subtle guidance tended to be strongest among relatively traditional female clinicians ($p<.10$).

The impact of varying the patient's gender was surprisingly slight. The patient received a better prognosis ($p<.05$) and elicited slightly more empathy ($p<.10$) when identified as a woman. In addition, the group atmosphere option was preferred more when the stimulus person was identified as a man ($p<.05$). The degree to which the patient's sex influenced the reactions of therapists depended on the latter's own sex in three instances. Female therapists tended to empathize more strongly with the female-designated than with the male-designated patient; they showed more empathy than male therapists did ($p<.10$) regardless of how the case materials were labeled. Women used behavior change more often with the female-identified than with the male-identified stimulus person and more often in general ($p<.10$) than men did irrespective of the patient's sex. Interestingly, role playing was slightly more popular in the case of opposite-sex than same-sex therapist-patient dyads ($p<.10$).

Relatively traditional clinicians preferred leader feeling slightly more than nontraditional clinicians when the patient was identified as a man, whereas the reverse held when the patient was identified as a woman ($p<.10$). Relatively traditional therapists also were more partial to behavior change with the female than with the male patient, and than nontraditional therapists tended to be ($p<.10$) irrespective of the patient's sex. The female patient was more likely than her male counterpart to elicit a behaviorally focused reaction from traditional female therapists and than either stimulus patient was from any other therapist subgroup ($p<.05$).

DISCUSSION

Previous research (2) supported the assertion that the clinical enterprise is susceptible to the proclivities of the mainstream culture that sanctions it (13). Our data suggest that the amount of sociopolitical bias among experienced group therapy practitioners is comparatively small. The impact of the patient's sex on the therapists' reactions was, for example, quite mild. This outcome may be a function of the respondents' collective clinical wisdom, their predominantly analytically oriented training that presumably included awareness of countertransference phenomena, their sensitization to the recent outpouring of professional concern over possible sex bias in psychotherapy, or limitations of the experimental procedures. Generalization is always a hazard when an analogue task requires professionals to participate vicariously in a clinical encounter. Manipulation of the sex variable within the context of a written clinical profile may have been a subtle cue, and the professional sample may have been too homogeneous in social values to permit a meaningful differentiation. Likewise, a substantial number of subjects may have suspected the true goal of the research despite precautions taken to the contrary, and monitored their responses accordingly. However, positive findings from similarly conceived studies tend to reduce the cogency of such reservations.

Certain isolated patterns in the data offer some support for the notion of sex-role-related countertransference (7). Female rather than male therapists were less disposed to use an overtly directive response (clarification-confrontation) but more disposed to use certain responses whose directiveness is institutionalized by theory (psychodynamic interpretation, behavior change) and certain covertly controlling responses (subtle guidance, group dynamics question). This configuration parallels conventional sex-role prescriptions for assertion and suggests that professional training and status may not guarantee insulation of therapeutic reactions from incorporated sex-role ideals.

Enhanced interpersonal sensitivity, an often cited outcome of feminine socialization, may differentially equip women with a valuable professional commodity. Both in this study and in an earlier study of psychother-

apy trainees (14), men could not marshal as much empathy for a stimulus patient as could women. This questionnaire differential could, however, also be accounted for in terms of sex-role pressure for women to present themselves as nurturant.

Predilection toward use of role playing with an opposite-sex patient is intriguing, all the more so because an identical finding for another Gestalt-type response (nonverbal) nearly achieved statistical respectability ($p<.12$). Research tends to confirm that encounter group participants are aware of an element of sexual play in such exercises (15). Whether or not therapists' preferences for these procedures are partly determined by their voyeuristic needs is an issue that should be tested among sensitivity group leaders.

APPENDIX 1
Group Therapist Response Alternatives from Wile Group Therapy Questionnaire (11)

Category	Response
1. Silence	Do nothing.
2. Group directed	Ask why no one has said anything about the fact that someone is crying.
3. Reassurance-approval	Express concern and reassurance.
4. Subtle guidance	Continue as if nothing out of the ordinary were happening.
5. Structure	Suggest that it might be more useful for him/her to talk than just to cry.
6. Attack	Accuse him/her of putting on a show.
7. Member feelings	Ask about feelings (e.g., encourage him/her to give words to his/her feelings; ask the members how they feel about his/her crying).
8. Leader feelings	Say how you are feeling (e.g., moved, embarrassed).
9. Leader experience	Share a similar experience in your own life.
10. Clarification-confrontation	Ask him/her why he/she is crying.
11. Group dynamics question	Ask them to describe what is happening at that meeting.
12. Group atmosphere	Say that someone in the group is crying.
13. Group dynamics interpretation	Describe his/her crying as an act of involvement in the group and a willingness to share his/her more private feelings with them.
14. Psychodynamic interpretation	Suggest that he/she may feel that the only time people are willing to listen and pay attention to him/her is when he/she is crying.
15. Personal life	Encourage him/her to talk about the events in his/her life that may be upsetting him/her.
16. Past and parents	Encourage him/her to relate what he/she is feeling to his/her family relationships and past experiences.
17. Behavior change	Encourage him/her to talk about his/her difficulties in behavioral terms.
18. Nonverbal	Use a nonverbal procedure to explore the rich emotional experience of crying.
19. Role playing	Ask him/her to role play the situation that he/she is crying about.

Anticipating the Impact of Public Law 93-641 on Mental Health Services

BY ARNOLD MILSTEIN, M.D., M.P.H.

Implementation of the new federal law setting up Health Systems Agencies (HSAs) on a regional basis offers many opportunities for participation by psychiatry. On the basis of interviews with mental health service providers, planners, and citizen representatives, the author formulated an inventory of the law's potential impacts, grouped around six general themes. He discusses the positive aspects of each, along with possible problems and hazards.

THE NATIONAL HEALTH PLANNING and Resources Development Act of 1974 (PL 93-641) is expected to have a major effect on the delivery of mental health services. Regarded as the federal government's most significant health initiative since the passage of the Medicare law in 1965, PL 93-641 establishes a coordinated health planning network at the regional, state, and national levels. The network replaces three major federal health programs: Comprehensive Health Planning (CHP), Regional Medical Programs, and the Hill-Burton Act authorizing the construction of hospitals. In addition to planning, this new network is charged with responsibilities for regulation and development of resources.

The cornerstone of the network is the Health Systems Agency (HSA), a regional health planning unit run by a governing body with a professional staff of at least five and a consumer majority. Each HSA will assess the existing health services system in its area, prescribe short- and long-range plans for the system's improvement, and use its limited authority, development funds, and technical assistance to bring its plans to fruition. Included in the HSA authority is the power to approve or disapprove federal grants under the Community Mental Health Centers Act on the basis of their harmony with HSA plans.

An HSA will be designated for each of the 202 health services areas approved by the Department of Health, Education, and Welfare in August 1975. Generally, HSAs will be either private nonprofit community agencies or public agencies under the auspices of single or legally joined unit(s) of local government whose jurisdiction coincides with the boundaries of the health service area.

Implementation of the law, now in the formative stages, offers many opportunities for participation by the psychiatric community. An awareness of the law's potential impact on mental health services will provide not only an antidote to "future shock" but also a basis for increasing the effectiveness of such participation. The following inventory of the law's potential consequences is intended to serve these purposes.

I constructed this report from interviews with 40 individuals representing the major groups at the interface between mental health services and HSAs, including citizens representing mental health interests, public and private mental health service providers, and mental and general health planners.

The types of impact that were predicted may be grouped around six general themes: 1) joint planning of mental and physical health services, 2) the relationship between HSAs and existing mental health service planning mechanisms, 3) emphasis on evaluation of mental health services, 4) more consumer input into mental health services planning, 5) increased availability of technical expertise for planning mental health services, and 6) emphasis on regional planning.

JOINT PLANNING OF MENTAL AND PHYSICAL HEALTH SERVICES

A combined planning approach promises three principal benefits. First, the clearly established clinical relationship between physical and mental health services (1) can be better exploited. Second, the wider political support base enjoyed by physical health services represents a new constituency for mental health services. Third, joint planning may hasten the development of a partnership between physical and mental health services necessary for creating generic primary care systems to treat "human problems" whose causes and solutions defy the prevailing boundaries of our health care system.

However, some broad dangers related to combined planning are anticipated. A narrow, traditional view of health and health care (2, p. 1217) may dominate, leading to several secondary threats. Inappropriately nar-

Dr. Milstein is Mental Health Career Development Fellow, National Institute of Mental Health, and Special Assistant to the Director, Division of Resource Development, Public Health Service, Region IX, Department of Health, Education, and Welfare, 50 Fulton St., San Francisco, Calif. 94102.

The views expressed herein are those of the author and do not represent the official positions of the National Institute of Mental Health or the Public Health Service.

row outcome criteria and a constricted range of interventions could be foisted on mental health services. These would not only fail to reflect the complex systems in which mental health and illness are empirically defined (3), but would also ignore much that has been found desirable about the community mental health movement (4, p. 48). Another secondary threat lies in the tendency of the traditional viewpoint to underrate psychological problems and shortchange their treatment. This threat would be accentuated if funds for physical and mental health services were pooled. Finally, health care may be based in institutions, thus endangering the gains made by the community mental health movement and saddling mental health services with an inappropriate share of medical center overhead costs, which tend to be high. A second threat emerges if sufficient funds to enable adequate planning for mental and physical health are not appropriated. If a funding famine materializes, short-rationing of funds for mental health planning may be less visible and therefore more politically feasible than it would be if mental health planning funds were identifiable as a discrete item.

HSAs AND EXISTING PLANNING MECHANISMS

Important benefits are expected to arise from the relationships between HSAs and state and county health and mental health departments and community mental health centers (CMHCs). Duplication of common planning tasks can be avoided, and a common planning format can be employed. Reason, rather than tradition or territoriality, can dictate the allocation of problem analysis and intervention functions to various planning levels and sectors.

Three principal dangers may be foreseen. First, the fact that nonfederal mental health monies are beyond the jurisdiction of the HSA may undermine coordinated planning among highly interdependent systems. Indeed, it is a meaningless exercise to examine CMHC functioning in isolation from state mental health policy in most regions. Second, state and local mental health planners, anxious or angry over their loss of autonomy to the HSAs, may engage in wasteful competitive planning. Finally, the mental health planning mechanisms already (or potentially) functioning well in such states as California and Arizona may be subject to wholesale replacement by the HSAs, or there may be indifference to their further refinement.

EVALUATION

To those who believe that the technology for meaningful mental health service evaluation exists and that this process is financially feasible, PL 93-641 represents an opportunity to better recognize effective components of mental health services. Those with a more pessimistic view of the technology of evaluation fear the creation of incentives for meaningless evaluative criteria. A second hazard derives from the fact that the outcomes of mental health services are inherently less tangible than those of physical health services. As evaluative efforts increase, mental health services may begin to appear less effective than physical health services. This appearance may be based largely on differences in ability to measure rather than on the actual value of the service. With a shared funding pool, the position of mental health programs in competing for funds may be compromised and the danger of their being shortchanged may increase. Another danger is that the informational demands of increased evaluation efforts may threaten the privacy of psychotherapeutic relationships.

CONSUMER INPUT

Since HSA governing board members may be better able to empathize with consumers of mental health services (and in some cases will themselves be consumers), the acceptability and utility of the services should increase. The range of intervention options is also likely to increase with consumer involvement. This prediction is based on two arguments. First, the professional's intervention horizon is inevitably narrowed by his own professional perspective as well as by the need to protect his turf, maintain referrals, and build interagency allegiances, whereas the consumer's is not. Second, while treatment options that are highly visible in the community (e.g., halfway houses) may often be volunteered by citizens themselves, the same proposals may be quashed by the community when they appear as an initiative taken by professionals or agencies (5). A final benefit is that well-informed citizen majorities on governing boards can provide a relatively neutral and democratic mechanism for resource allocation since they tend to have less intense specialty, agency, or program loyalties.

Several dangers are anticipated in this context. The consumer viewpoint may be inadequately represented—as it has been on some CHP and CMHC governing and advisory boards—because of intimidation of consumer representatives by health professionals. The heralded intent of PL 93-641 to solve this problem may lull the general public into trust (which may prove to be unfounded) that these threats to democratic planning are behind us and thus may deter efforts to strengthen consumer participation. Ironically, strong consumer participation can itself pose a threat. Consumer board members unfamiliar with social planning may fail to make appropriate distinctions between overall setting of priorities and internal management functions, at a significant cost to both processes.

TECHNICAL EXPERTISE FOR PLANNING

There are many opportunities for coordinated and effective social planning in the HSA-mental health serv-

ices interface. In relation to mental health services, the benefits could range from more rapid progress toward societal goals that are contingent on effective mental health programs to more prosaic results like better coordination and cooperation among diverse mental health service programs. Other benefits include a better data base for decision-making and improved tools for internal management at program and agency levels.

The greater availability of technical planning resources is not without potential problems. Citizens' lack of education and experience in social planning may limit their ability to use the sometimes complex and technical outputs of planning staffs meaningfully (6). Problems of this type also arose in regard to CHP. The abstract, intangible nature of mental health services compounds the problem of noncomprehension by members of HSA governing boards.

EMPHASIS ON REGIONAL PLANNING

The health service areas mandated by PL 93-641 will be an appropriate scale (2, pp. 294-296) for the understanding and solution of important problems in mental health service delivery (e.g., treatment of individuals requiring long-term psychiatric hospitalization). Also, given a fixed amount of dollars available for health planning, the regional scale increases the financial feasibility of having specialty area planners on HSA staffs. In many health services areas it will be possible to employ a mental health planner. In addition, the larger the area for which plans are developed, the larger the potential political constituency for the plan and the more difficult it will be for policy makers at state and local levels to ignore mental health needs.

However, several liabilities appear to be associated with regional planning. Problems or solutions whose boundaries are those of a county, city, or catchment area may not be appropriately delegated by an HSA. This could occur for several reasons, including a misperception of the most appropriate scale on which to approach an issue or an HSA's overzealous guarding of its legal jurisdiction. Demoralization and apathy could plague existing governing or advisory boards of CMHCs, which might see HSAs as a threat to their sense of autonomy. An important source of input from experienced people working at the subregional level could thus be lost to the larger process of regional planning. A third anticipated danger is that in politically conservative regions, small, poor communities could be deprived of CMHC funding by a regional governing board that is averse to committing local tax revenues to support a CMHC as the levels of federal grants decline. Since the federal government is often the only available source of fiscal support to initiate these services, this "tyranny of the majority" could bring about serious inequities in the mental health service system. A fourth danger may be subsumed under the label "complex system problem." Mental health services are already highly related to many other human service components at several levels (e.g., county probation departments, city jails, state Medicaid programs, and state rehabilitation programs). Adding a new level of aggregation and a new entity with which to relate will definitely increase the complexity of the human service system while offering only a possibility of improving its functioning.

CONCLUSIONS

An awareness of the major forces that shape the conduct of an individual's life is perhaps the psychiatrist's most common "prescription." Public policies are exerting an increasing impact on the practice of medicine. Psychiatrists would thus do well to recommend the same elixir for themselves in relation to future external forces as they do for patients in relation to their past and current internal forces. The anticipated impacts I have outlined provide an initial assessment of major opportunities for, as well as dangers to, the successful delivery of mental health services.

LETTERS TO THE EDITOR

A Modest Proposal

SIR: I wish the assistance of the *Journal* in conducting a market survey among potential buyers of a new product that promises to be of great use to all practicing psychiatrists, especially those in California.

While reflecting recently upon the plight of our West Coast brethren, a colleague and I came up with a method for notifying potential victims of psychiatric patients who make homicidal threats within earshot of a psychiatrist. Before attempting to sell our idea to Hallmark Cards, we would like to test consumer reaction. Here is our idea.

A tasteful, attractive card bearing the legend "Someone Is Thinking Of You" on the front would, on the reverse side, inform the reader that "A Certain Person has told Dr. _____[space to be imprinted with the psychiatrist's name, office number and provider code] that he wishes to __intends to __or has tried, failed, but is about to try again to __kill you." The sender would check the appropriate space.

As your readers can see at once, this method not only delivers the warning required by the new state law in California but discharges this obligation in a tactful and uniform manner. As an additional service to customers, a detachable card would be retained by the psychiatrist for his records in case he was challenged on compliance with the law.

We hope that if our idea catches on greeting card displays in drugstores and the like will soon have a section marked "Death Threats" (perhaps somewhere between "In Memoriam" and "To My Son the Doctor") displaying a selection of styles.

We would appreciate letters from *Journal* readers telling us how they like this idea. Also, we would like to mail out a test batch to members of the California legislature, since, at a recent medical meeting, one of us distinctly overheard a homicidal threat uttered by a physician who gave every evidence of mental instability, a threat that seemed to be aimed at any or all members of the body that passed the law in question.

DOUGLAS A. SARGENT, M.D.
Thanatos Greeting Card Project

Insuring Psychiatrists

SIR: Several years ago, many of us wondered why the Association decided to change insurance carriers for the group malpractice insurance with a resulting tripling of premiums. Despite the thousands of words that have been written and spoken on the subject, the reasons for this change have not been made clear. Shortly thereafter, it became apparent that some of the increased premium was going to pay for the massive advertising campaign by the Joseph A. Britton Agency, which included sending representatives to the APA annual meetings in Hawaii and Anaheim and placing full-page ads in APA publications.

The final blow has now been struck with the publication of "Professional Liability Insurance and the American Psychiatrist" by Chester L. Trent, M.D., and William P. Muhl (December 1975 issue). Although the *Journal* is supposedly a scientific publication, this article is nothing more than further advertising for the insurance carrier and for the APA-sponsored group policy.

I object to the premium dollars being spent on advertising, and I object even more strenuously to free advertising in the pages of the *Journal* under the disguise of a scientific or informative article.

GEORGE BAJOR, M.D.
Encino, Calif.

SIR: I think it curious indeed when a representative of the American Psychiatric Association teams up with a representative of the insurance industry to explain and justify APA's position on professional liability coverage for American psychiatrists. I am pleased that such coverage is available to APA members like myself, but in no way am I convinced that Dr. Trent and the Committee on Member Insurance and Retirement Plans represented their constituency well by approving outrageous premium hikes in 1975.

This article has increased my doubts. It reveals the very low incidence of malpractice suits against psychiatrists and also the relatively low dollar awards in successful suits. I feel it is specious to determine premiums on anything other than relevant actuarial data, but the article did not address this issue. Instead, it speaks of the claims consciousness and legal sophistication in this country, of a glut of hungry lawyers, and of even more nebulous matters such as civil rights and public advocacy.

Rather than an apologia coauthored by Dr. Trent and Mr. Muhl, a spokesman for the insurance business, let Dr. Trent tell APA members how the new premium rates were negotiated and why he believes that premiums should be based more on prophesy than on facts concerning claims experience for psychiatrists.

BRIAN LIPTON, M.D.
New York, N.Y.

Dr. Trent Replies

SIR: In response to Dr. Bajor, I would like to point out that the change from the previous program was effected to develop a nationwide professional liability program with a financially strong company that would be duly licensed in all states and would afford direct organizational participation.

To achieve this goal, brokers from the Joseph A. Britton Agency are available at the annual meeting to answer members' questions about the program (a service to members), just as other members of APA staff, as well as representa-

tives from other APA programs, drug houses, book companies, etc., attend the meetings. All of this activity is an important aspect of any annual meeting.

From a business point of view, the larger the participation in our program, the more actuarially sound it will become. Any promotional effort that furthers this goal is truly a member service.

This program operates on a 21% expense factor, which means 79% of each premium dollar is available for loss payments. This ratio is superior to that of similar programs. Advertising space in *Psychiatric News* has been provided to this program without charge in order to obtain a part of the highly favorable loss ratio. Expenses would otherwise have been greater.

The committee appreciates the plight of physicians—especially in the states of California, Florida, New York, and Ohio, where premium increases have been large—and is mindful of the financial burden. In the current malpractice climate, however, APA is fortunate to have a national program (except for those states now eliminated by law) to offer at any price.

The pertinent questions raised by Dr. Lipton have also been voiced by many others. Mr. Muhl is with the Joseph A. Britton Agency, the official broker for the APA-sponsored program. He reviews all the official data about APA claims and losses on a daily basis. It is only natural to coordinate a description of our program with its chief operating officer.

Current premium rates for the APA program are based on a 1972 formula adopted by the APA Board of Trustees and Chubb and Sons agreeing that rates in each state on an annual basis would be 60% of Class I (general practitioners) Insurance Service Organization rates, or 25% of the leading carrier, such as a medical society program (in New York, California, and Florida, this rate is 10% below such leading carrier rates because of special problems in these states). Thus the initial rates were set to reflect losses lower than those of other Class I practitioners. In addition, it was agreed that the program would operate on a 75% loss ratio, which was recently revised to 79%. Thus, 21% of each premium dollar goes for expenses and 79% would be utilized for losses. Self-rating is expected when adequate, credible data on the program claims become available.

Current premium increases systematically reflect the above formula. If APA psychiatric losses prove to be less than anticipated—and current experience appears favorable—there is hope for a future premium reduction, provided psychiatric claims and inflation do not continue to escalate. Thus, the APA program was designed from the outset to be based on the most solid actuarial bases possible and has been heading in that direction since September 1972 at the fastest possible rate. Unfortunately, because of the long tail of malpractice, it takes several years to accumulate credible data. If current premiums ultimately prove to be overestimated, 79% of APA members' premium dollars are earmarked for actual APA losses and will be utilized in future premium adjustments based on actual data when accumulated.

Psychiatrists might also be interested to know that before 1975 it was not necessary to report psychiatric claims separately from Class I (general practitioners) claims. This explains why there were no previous systematic data on psychiatric losses that could be used for setting current premiums more accurately.

CHESTER L. TRENT, M.D.
Chairman, Committee on Member Insurance and Retirement Plans

Editor's Note: Like all articles submitted to this journal, the article by Dr. Trent and Mr. Muhl was subjected to our review process. The reviewer, who has a law degree as well as a medical degree and is a nationally recognized forensic psychiatry expert, made the following comment about the paper: "The subject is important, particularly since it involves APA activity in an area essential to medical practice." He recommended publication and assigned the paper a high priority.

Is Countertransference an Appropriate Issue in Clinical Supervision?

SIR: In "Countertransference: A Neglected Subject in Clinical Supervision" (January 1976 issue), Marcia Kraft Goin, M.D., and Frank Kline, M.D., discussed a very important and perhaps not well utilized area in supervision.

However, the article did not seem to assess the reasons why the supervisors did not use countertransference interpretations. Fear of being the trainee's therapist was mentioned, but a very natural reason for avoiding countertransference interpretations was not. The study has documented and the positive responses of the residents whose supervisors did deal with these issues—but what about those residents who do not respond so positively? Are there no such cases? What are the casualties, the risks of such negative responses, and their effect on the further learning abilities of such residents? I am surprised that the trainee's own negative response or resistance was not given as a possible (and perhaps the most appropriate) reason to avoid delving into countertransferences.

U.P. BHATT, M.D.
Riverside, R.I.

Dr. Goin Replies

SIR: Do supervisors avoid making countertransference interpretations because they fear the residents will respond negatively? Dr. Bhatt's letter raises a very important issue that I am glad to have the opportunity to clarify.

Residents are often offended when supervisors make any kind of interpretation about their attitudes, feelings, or behavior. They experience the interpretation as an attack, or they feel they are being put into the patient role, with all the attendant fears and anxieties this role arouses but none of the usual reassurance that the therapist will work with them until the conflict is fully resolved. We were not suggesting that supervisors make countertransference interpretations but that they provide an atmosphere in which the resident can feel free to talk about his or her feelings and not avoid the subject when it is brought up by the resident. We also believe that a supervisor should tell a resident when he thinks a countertransference reaction is distorting the therapeutic interaction.

The videotapes that we looked at showed several instances in which residents wished to talk about countertransference and their supervisors avoided the subject. The tapes also showed one session in which the way the supervisor approached the subject was certainly counterproductive, particularly because it did not allow for open discussion.

Those supervisors who were successful in their discussion of countertransference had a good working relationship with their residents and an attitude of colleagues learning togeth-

er. In this situation, if a trainee did not feel comfortable about pursuing the subject, the discussion of countertransference was dropped and this did not disrupt the teaching-learning relationship.

MARCIA KRAFT GOIN, M.D.
Los Angeles, Calif.

Reporting Side Effects of Imipramine in Children

SIR: In "Blood Pressure and Pulse Changes in Hyperactive Children Treated with Imipramine" (December 1975 issue), Lawrence M. Greenberg, M.D., and Absalom M. Yellin, Ph.D., reported increases in these measures. In the May 1975 issue of the *Journal*, Winsberg and associates (1) reported very clearly that cardiac effects of imipramine are related to the milligram per kilogram dosage given.

Drs. Greenberg and Yellin did not give any information on the weights of their patients, and in their experimental design they used a dosage of 100 mg/day, which is unusually high for the average child. In our description of the use of imipramine for childhood behavior disorder (2), the average dose used was 50 mg/day. Also, in the May 1975 issue, Hayes and associates (3) stated that imipramine dosage in children should be reported in milligrams per kilogram. Their study indicated that a dosage of 3.3 mg/kg appeared to be safe. Our experience with the use of imipramine for both behavior disorders and enuresis indicates that in a large percentage of cases the therapeutic dosage is well below this limit.

HANS R. HUESSY, M.D.
Burlington, Vt.

Drs. Greenberg and Yellin Reply

SIR: The mean daily dosage of imipramine in our study was 3.6 mg/kg, with a range of 2.2–5.9 mg/kg. Methodological considerations guided us in our decision to use the same maximum dosage for all the children, who were very closely monitored throughout the study (1). Analysis failed to reveal any significant dosage/weight interactions. However, Dr. Huessy's concerns are most appropriate. Our concern was to point out that the treatment of hyperkinesis with imipramine deserves additional study in terms of both side effects and behavioral effects. Our data on side effects (reported in the article Dr. Huessy is commenting on), performance (2), and behavior rating (3) indicate that imipramine may not be the medication of choice with respect to the more important target symptoms of hyperkinesis, such as attention span and distractibility, and that the seeming efficacy of imipramine with respect to overactivity may be related to sedation effects. Others have also voiced similar concerns (4).

Should Intensive Psychotherapy Be Insured?

SIR: In "Insuring Intensive Psychotherapy" (December 1975 issue), Steven S. Sharfstein, M.D., and Howard L. Magnas offered some useful data. However, I question some of their conclusions.

They estimated that only 0.9%–1.1% of all psychiatric outpatients covered by a large health insurance plan (the Blue Cross/Blue Shield plan for federal employees) required intensive psychotherapy and that this activity consumed only 8.7%–10.3% of the total cost for physicians' treatment of mental disorders. Intensive psychotherapy was defined as expenditure of more than $6,000 a year for outpatient psychotherapy (roughly 150 visits a year at $40 a visit). From these data, the authors conclude that it is feasible to finance intensive psychotherapy under a comprehensive health insurance program.

I must acknowledge that my interpretation of their data is biased by my experience in a prepaid mental health system wherein more than 95% of patients with emotional problems can be effectively treated within 20 outpatient visits a year. Interestingly, the authors' data also suggest that practitioners in the indemnity sector find that the majority of their patients respond to brief psychotherapy—approximately 79% of their patients were treated at an annual expenditure of less than $999 or within fewer than 25 visits. Unfortunately, the remaining 21% of patients consumed more than two-thirds of the total cost for outpatient treatment.

Could we not apply the description "long-term" to the patients who used more than 25 visits a year? By using this label only for those who consumed more than 150 visits a year, the authors have made an arbitrary decision that shapes all of their subsequent arguments.

Given the gradual inflation of health care costs, it is difficult to be sanguine about the cost-effectiveness of mental health delivery, at least as it is revealed by the authors. The percentage of psychologically impaired people in a given population ranges (depending on the degree of impairment) from approximately 20% to 80% (1, 2). We also know that the initiation of help-seeking behavior, the form of that behavior, and the response of care providers is controlled by many factors other than the intensity of the patient's need for help (3). When the authors imply that utilization of mental health services has stabilized at a cost less than 7.3% of the total benefits, we must be aware that the actual number of patients involved is probably only a small fraction of those patients who could potentially use such services. Whatever stability has developed in the past 3 years may change

with changes in provider attitudes and patient receptivity to mental health services. Thus I question the authors' confidence that "It is clear that in this system, which offers a comprehensive benefit . . . the numbers of people electing high cost psychotherapies as the treatment of choice remain consistently low—a self-stabilizing factor mitigating against threats of exorbitant overutilization of the mental health benefit."

In addition Dr. Sharfstein and Mr. Magnas do not seem to appreciate the fact that by sanctioning an open-ended system of insuring psychotherapy (controlled only by peer review), they are sanctioning longer term treatment at the expense of the development of shorter term modalities. Several factors operate to bias therapists toward long-term treatment. First, therapists tend to view long-term treatment as being more comfortable and convenient because patient turnover and the effort involved in assessing patient problems and treatment goals are less when one sees fewer patients. Second, patient dependency needs are more readily indulged in long-term treatment. Third, permissiveness toward long-term treatment biases the process of psychotherapy because therapists are not challenged to develop short-term treatment skills. Finally, when therapists' calendars are filled with long-term treatment cases they are accessible to fewer patients who need help.

When we consider the absence of adequate outcome studies justifying the choice of long-term over short-term psychotherapy, sanctioning of long-term treatment without financial constraints becomes specious.

THOMAS E. BITTKER, M.D.
Phoenix, Ariz.

SIR: Dr. Sharfstein and Mr. Magnas note that prior experience with insurance for intensive psychotherapy demonstrates that few patients will utilize this therapy. They also make an analogy between such intensive psychotherapy, at a cost of $6,000 a year, and catastrophic medical illness. This analogy is overly broad. "Catastrophic" medical illness means just that—a medical and financial catastrophe. Public policy supports the great cost of care in such catastrophes as renal failure, long-term dialysis, and renal transplant. In contrast, psychoanalysis deals with minor problems in psychoneurotic individuals who do not have major "ego defects." These patients are predominantly bright, young, verbal, successful, and have incomes considerably above the national median.

The authors also pointed out the need for better diagnosis and definition of therapeutic goals for such treatment. In a free society, an individual who is suffering from anxiety is free to undergo any treatment or educative process he wishes. It is an entirely different matter to ask the insurance industry and, ultimately, the vast majority of policy holders who would never choose psychoanalytic therapy to bear this financial burden.

According to Dr. Sharfstein and Mr. Magnas, "Health care is a right and, as such, includes the right to improved well-being. Limiting mental health care coverage under health insurance limits that right and diminishes the opportunities for total human growth and development." This rhetoric is garbage. Obviously, human growth and development are limited by myriad factors, including the economic cost of many growth-promoting experiences.

Health care is much too serious a concern to be jeopardized by such dubious claims as those the authors have made. There are crying needs for financial aid in the treatment of schizophrenia, mental retardation, and child abuse—to name just a few areas. Physicians are needed to aid the poor in the urban ghetto and in isolated rural areas. In the absence of scientific proof of the efficacy of psychoanalysis, there is no policy value in subsidizing an expensive, intensive psychotherapy for minor conditions in a privileged few.

WILLIAM L. ALLAN, M.D.
West Chester, Pa.

Dr. Sharfstein and Mr. Magnas Reply

SIR: In our paper we did not take up the issue of the type and degree of illness that analytic patients bring to treatment. There is now some evidence that these patients are indeed sick and in need of treatment rather than suffering from minor problems, as Dr. Allan suggests. In a Joint Information Service publication, it was estimated that 83% of analytic patients were moderately to severely impaired (1). To the extent that psychoanalysis is a growth and educative experience, its coverage under insurance should be limited or eliminated. However, to the extent that it is a treatment for very impaired, suffering individuals, it deserves no less coverage than any other medical treatment. One might ask Dr. Allan why it is that psychoanalysis, invented 60 years ago, continues to be practiced primarily by physicians rather than educators or "self-actualizers."

We did emphasize in our paper the need for outcome studies to prove the efficacy of such expensive treatment. This is no less true for any other expensive medical treatment.

Dr. Bittker's letter deserves perhaps another study comparing psychotherapy in prepaid medical health systems and psychotherapy in fee-for-service insurance mental health systems. Clearly, when one has a fixed budget and personnel contraints, practice changes and there is little opportunity for the "luxury" of long-term psychotherapy. Perhaps "intensive psychotherapy," which implies a specific treatment that attempts major personality change in a severely emotionally ill individual, is a better description than "long-term psychotherapy." Dr. Bittker's point about the prevalence of psychologically impaired people seems to miss the mark. What is more specific is the "treated prevalence" or utilization by a subpopulation such as federal employees, who are at high risk for undergoing psychotherapy because they are well-educated and highly verbal. In spite of being at high risk and more likely to use available benefits, the utilization and costs of long-term psychotherapy in this group have predictability and stability, which should enable insurance actuaries to compute premiums and consumers to decide whether they want to pay the few pennies extra in order to have the opportunity for psychotherapy, both short term and long term.

We fail to see Dr. Bittker's point that sanctioning long-term treatment will be detrimental to short-term modalities.

We are more concerned with Dr. Allan's point that the needs of other very impaired individuals, with schizophrenia, mental retardation, and other conditions that make them poor candidates for psychotherapy, will be neglected because highly skilled physicians would prefer to treat very impaired neurotics by psychotherapy. We must be increasingly concerned with the overall scarcity of resources and the fact that there is no sure way to ensure equity of access to high-quality care. However, the lesson of the Federal Employees Program is clear: In a large insured population, intensive psychotherapy is insurable and will have predictable utilization and stable costs.

Viral Encephalopathy and Psychosis

SIR: The article "Viral Encephalopathy Mimicking Functional Psychosis" by Lawrence G. Wilson, M.D. (February 1976 issue), strongly suggested an association between herpes encephalitis and catatonia. In our review of four patients admitted to a psychiatric service with an initial diagnosis of acute psychosis, and later diagnosed as probably suffering from acute viral encephalitis, we were struck by several features that bear further emphasis. As in two of Dr. Wilson's cases, the diagnosis of herpes encephalitis could only be strongly suspected in two of our cases on the basis of the clinical evidence and the EEG. In a third case, postmortem examination was confirmatory. Serum antiherpes antibody titers were not obtained.

Of our three cases of suspected herpes encephalitis, none presented with catatonic features. One patient became acutely gradiose and paranoid, and exhibited bizarre and obscene behavior (he masturbated and smeared feces). Another was acutely excited, bizarre, and obscene (he masturbated openly). The third patient had auditory hallucinations and was paranoid. While the first two cases might resemble cases of catatonic excitement, there were never periods of catatonic rigidity, and the paranoid and grandiose features of the mental status of all three patients were impressive. A fourth patient did present catatonic and hebephrenic features, but after an initial suspicion by the psychiatric service of organic encephalopathy, careful medical evaluation including serology for viral antibodies and an eventual postmortem examination led to the diagnosis of subacute sclerosing panencephalitis (1). Based on these experiences, we suggest that herpes encephalitis need not present with catatonic rigidity or stupor, and conversely, that catatonia can be associated with other viral encephalitides.

In reviewing our cases, it was instructive to discover what information was most helpful diagnostically. All cases presented as subacute change in mental status and behavior that evolved within one or two weeks in previously normal young adults or adolescents. The mental symptoms were not typical of functional psychoses: hallucinations included olfactory and auditory illusions; there was remarkable disinhibition of behavior, with acute loss of verbal, social, and sexual continence (and later, urinary and fecal continence); and profound regression more typical of chronic schizophrenia. Many of the symptoms were associated with a feeling of strangeness and impending doom. These features suggest pathological changes in the temporal and frontal lobes. Only later did neurological findings come in to the picture. First, there were clonic, focal, or versive seizures, altered consciousness, increased muscle tone and tendon reflexes, and Babinski sign. Frontal lobe signs (snout, suck, and grasp reflexes), frontotemporal slowing in the EEG, and mild cerebrospinal fluid lymphocytosis and increased protein with a low-grade fever appeared even later; there were never signs of meningismus. Skull films, carotid angiography, computer-augmented tomographic radiography, and brain biopsy were not helpful in any of the cases. None of the patients had prior herpetic skin lesions.

In conclusion, it is not reasonable to assume that an acute psychosis or the syndrome of catatonia is schizophrenia. Since many encephalopathies are treatable and even the chemotherapy of viral encephalitides is making some progress, it is increasingly important to suspect acute viral and other organic encephalopathies in the differential diagnosis of all acute psychoses. It is particularly important to emphasize that psychiatrists have the most powerful diagnostic test to pick up such cases early—the careful mental status examination.

Practicing What We Preach

SIR: The overviews by John M. Davis, M.D., in the December 1975 and January 1976 issues of the *Journal* on maintenance therapy in schizophrenia and affective disorders are timely from more than one perspective. It is reassuring to see that research and therapeutic outcome studies are beginning to result in clear findings, such as the following: "The evidence that lithium prevents recurrence of manic-depressive illness has . . . been established beyond the shadow of a doubt. Given that there . . . were several suicides in the placebo groups, further replications of the above finding would only reincur these risks needlessly." Later in the article, Dr. Davis stated, "*In general it appears that lithium is approximately equally effective in unipolar and bipolar patients.*"

The above statements give clear guidance to the practicing psychiatrist. This letter is related to the nature of this guidance. More specifically, it seems that conducting placebo-lithium research or omitting the possibility of lithium therapy in any type of manic-depressive illness could be tantamount to malpractice. On the other hand, the Food and Drug Administration (FDA) has not approved lithium for use in unipolar illness.

I hope that most physicians do not practice medicine strictly according to the *Physicians' Desk Reference (PDR)* but rather use the *PDR* and the FDA as agents of informa-

tion. However, physicians do seem to view the FDA as a quasi-legal agency that somehow has regulatory power over the practice of medicine (1). Physicians appear to be practicing defensive-conservative medicine these days, and I wonder how many psychiatrists would never prescribe lithium in unipolar illness?

I feel that for these reasons specific questions need to be asked and faced.

1. Is the physician taking a malpractice risk by prescribing for indications other than those in the *PDR*?
2. If a physician prescribes for a reason not indicated in the *PDR*, should the patient always be so informed?
3. Is a physician taking a malpractice risk if he *avoids* prescribing in instances that the current literature would support?

There are other agents (e.g., propranolol, droperidol, and bethanechol) that are useful in psychiatric treatment. The above questions apply to these substances as well as lithium.

On the Boards Again

SIR: I agree with the recommendations and conclusions in "Experiences of Psychiatry Board Exam Casualties: A Survey" by Martin R. Lipp, M.D. (March 1976 issue).

Years ago, I talked with a number of candidates who passed the Boards and some who failed one or another portion. Those who failed were bitter, railing against the very poor quality of the choices of possible answers to the questions and also against the often obvious and occasionally vindictive biases or prejudices of the examiners.

One man was brilliant in his ability to memorize books of references, etc. During the orals, his sole task was to find out the "school" of the examiner and then to slant his exposition. He passed easily, but as a clinician he was a nothing.

When I worked for the Department of Mental Hygiene some time ago, I took a promotional examination. At that time, my orientation within the field of psychiatry was changing to a more physical and nutrients-disturbance etiologic approach. I suddenly found myself in empathic disarray with the examiners and realized my progressive disaffection with the field of psychiatry and my increasing discomfiture as a traditional psychiatrist. That was a devastating period for me. I eventually left state employ for private practice.

The psychiatric literature and I are increasingly at odds, to the point that I experience "psychiatry" as an alien intrusion. Given this, I could imagine the scenes should I attempt the Boards, which, in my opinion, do not reflect the individual's knowledge, skills, or comfort in working within the field of psychiatry. They reflect the expectations of a group of like-minded persons, the need for conformity, and the societal strength that comes from such conformity in addition to the biases and prejudices of the examiners and individuals who make up the questions.

The Boards should reflect capacity for work, thinking ability and range, creativity within working relationships, individual integrity and openness—the marks of an expert within his chosen field—without regard to someone else's preconceptions. I would consider standing for such a display of my thinking and working. Until then, I consider the Boards an onerous and unfair device for image projection to society, a restrictive device within the psychiatric profession, and an ego display to oneself.

GEORGE P. CONGRAM, M.D.
Dix Hills, N.Y.

Clarification

SIR: The closing sentence of "The Phasing Out of Mental Hospitals in the United States" by Milton Greenblatt, M.D., and Elizabeth Glazier, M.P.H. (November 1975 issue), points to the need for "accurate, standardized information regarding our present systems of care in order to make just and rational decisions regarding future allocations of scarce mental health resources." Consequently, we would like to inform *Journal* readers of a misunderstanding that might arise from appendix 2 of that article regarding Stockton State Hospital.

Although Stockton State Hospital is its legal name, its preferred name and the one by which it is known to the Joint Commission on Accreditation of Hospitals is Stockton Residential Facility. The facility consists of 18 units for the developmentally disabled (mentally retarded) and 2 units for the mentally disordered (mentally ill), not 2 units as suggested in the article.

The 18 units for the developmentally disabled serve all of California, not specifically "one county's program." In fact, San Joaquin County provides only approximately 27% of the residents of the units for the developmentally disabled. The 2 units for the mentally disabled do serve San Joaquin County by a unique leasing program for community mental health services. This program, in conjunction with the University of California, Davis, and the State of California, supplied a three-way contract that provided the residency training in our psychiatric education program.

The facility is academically involved not only with the nursing program at Delta Junior College, as was suggested in the article, but also with the nursing program at Modesto Junior College. It is also associated with the University of the Pacific, the University of California, Davis, and the State University at Sacramento in one or more of their programs in pharmacy, psychology, psychiatric residency, and social work.

We hope that this clarification abides by the spirit and the letter of the important article by Dr. Greenblatt and Ms. Glazier.

MICHAEL F. HEIMAN, M.D.
Stockton, Calif.
MARTIN A. JOHNSON, M.D.
Sacramento, Calif.

Dr. Greenblatt and Ms. Glazier Reply

SIR: We wish to thank Drs. Heiman and Johnson for clarifying and updating information regarding the current training and clinical program at Stockton State Hospital, now more properly known as the Stockton Residential Facility.

Although the standardized information called for in the closing paragraph of our article was intended primarily as a reference to standardization of state and federal statistical reporting systems, we agree that accurate information regarding types of programs is of equal importance. The abbreviated list of programs in appendix 2 of our article should have stated that the Stockton facility is currently academically involved with nursing programs at two junior colleges plus training programs in psychology, pharmacy, and social work at various other state institutions and that, although the program for the mentally ill serves only San Joaquin County, the program for the developmentally disabled serves all of California.

ELIZABETH GLAZIER, M.P.H.
Sepulveda, Calif.

Hiccups Following Ingestion of Oral Chlordiazepoxide

SIR: I recently treated a 19-year-old soldier with 10 mg of chlordiazepoxide four times a day for anxiety secondary to situational legal difficulties. At the time of his second interview he gave the following interesting report. Within one hour after taking his first chlordiazepoxide capsule, he noted the onset of hiccups. The hiccups persisted despite his use of the conventional home remedy of holding his breath. He continued the medication for three days, and during that time his only relief from the hiccups occurred during sleep. On the second day he was seen by his dispensary physician, was found to be otherwise in good health, and was told to initiate bag-breathing. This also failed to alleviate his problem.

On the third day the patient decided that perhaps the medication was the source of his problem. Approximately 5 hours after he discontinued the medication his hiccups ceased. Being a somewhat inquisitive sort of person, he decided to test his hypothesis with a drug challenge on the following day. Within an hour, his hiccups returned. They disappeared spontaneously after 2 or 3 hours and had not returned 2 weeks later.

Although Greenblatt and Shader (1) note that hiccups have been reported following intravenous administration of diazepam for induction of anesthesia, they made no note of hiccups as a side effect of oral diazepam or chlordiazepoxide. My own review of the literature has also failed to disclose any such reports. I would be interested to hear whether any other physicians have noted this side effect with oral chlordiazepoxide.

Triple Mosaicism of X Chromosomes in Bipolar Affective Disorder

SIR: I would like to report an instance of triple mosaicism of X chromosomes with severe bipolar affective disorder. I reported on another such case in 1973 (1) and discussed the possible relationship between X chromosome mosaicism and bipolar affective disorder.

The patient is a 30-year-old woman who had been in and out of mental hospitals until July 1974, when she was given lithium carbonate. She has been responding to lithium satisfactorily and is free of psychosis. She was given the diagnosis of manic depressive illness, manic type, during most of her stay in state hospitals.

Her mental status at the time of the manic phase was described as hyperactive and over-talkative, with flight of ideas to the point of incoherence at times. Some degree of expansiveness and grandiose delusions was also noted, but there was no evidence of hallucinations or autistic thought. The depressive phase was described as being agitated, with some degree of psychomotor excitation.

The patient had some physical indications of Turner's syndrome, including webbed neck and low hairline. However, she gave birth to two children, a boy and a girl, and classical Turner's syndrome includes infertility. Karyotyping revealed 45X0/46XX/47XXX mosaicism with 79% XO, 3% XX, 17% XXX, and 1% aneuploidy in 100 cells. Her 17-month-old daughter's karyotype is 46XX normal female.

The patient is one of six siblings, three males and three females. Her paternal grandmother resembled her physically but had no reported history of psychosis. The patient's family history is negative for the presence of affective disorders or other psychoses.

My experiences of two mosaicisms of X chromosomes in individuals with bipolar affective disorder support my speculation that certain subclinical types of bipolar affective disorder may be associated with the presence of X chromosome mosaicism—especially when XO cell lines and XXX cell lines exist in the same individual.

It will be necessary to find more such cases to establish a new disease entity in affective disorders. We are currently in the process of studying karyotypes of patients who reveal severe bipolar affective disorder with physical resemblance to Turner's syndrome (especially low hairline and short stature) and weak or negative family history of affective disorders.

"Waltons Syndrome"

SIR: I would like to share with your readers a new syndrome that has surfaced in the "last frontier" of Alaska and is related to contemporary economic conditions. Since the trans-Alaska pipeline boom began up here approximately two years ago, I have seen as patients a number of single men in their early twenties who have left their jobs in other areas because of the economic slump. These young men came to Alaska in an effort to make a lot of money and return home to help rescue brothers, sisters, and parents who are also experiencing relative poverty due to job losses. These patients are all very family oriented and conscientious and are the oldest children in their families.

The symptoms of these young men have largely been those of situational depression. The very high prices and living costs here have made it impossible for them to save nearly as much money as they had hoped. This is complicated by the sometimes very severe social and environmental aspects of life in Fairbanks with its long, cold winters (temperatures often drop below −50° F). I have generally used psychotherapy, antidepressant medications such as imipramine and amitriptyline, and occasionally, ECT to treat these patients. All of them have responded well to treatment. I see their depression as part of the maturing process rather than the beginning of any deep-seated problem.

These young men struck me as similar in attitude and disposition to John Boy, the hero of the television series "The Waltons," so I have named this type of reaction the "Waltons syndrome."

FRANCIS J. WHELAN, M.D.
Fairbanks, Alaska

In a Semantic Mood

SIR: Before I read "Affect, Mood, Emotion, and Feeling: Semantic Considerations" by Richard Ketai, M.D. (November 1975 issue), I had always thought affect was a display, mood referred to spirit, and emotion meant a feeling in a subjective sense. I stand corrected?

R.H. ISAAC, M.D.
Pasadena, Calif.

Dr. Ketai Replies

SIR: Dr. Isaac may stand corrected if he so desires. The reason for my article was to sort out the confusing and contradictory conceptualizations of these words as they are used in psychiatry. For every person who would agree with Dr. Isaac's definitions, there is someone else with an alternative idea, although neither is necessarily incorrect.

Words may signify whatever we define them to mean, the problem being to achieve consensus. I have proposed one way to define these words in order to understand and communicate about specific important concepts. My proposal was based on a careful review of pertinent literature, and the result reflects what I considered to be the best ideas of others integrated with what made the most sense to me. As far as I know, this is the only proposal that takes into account the multiple connotations of all these words. These include the scientific meaning of the words per se, the temporal features of the experiences reflected in the meanings of the words, the subjective-experienced meanings versus the objective-displayed meanings, and the distinctions between what is displayed and how it is displayed.

Thus when Dr. Isaac says he believes affect is a display I would not disagree—but I would emphasize that it is a transient display (affective display), that it is transiently experienced (affective sensation), and that it may be displayed in a variety of ways (affect quality). Mood may refer to "spirit" as Dr. Isaac suggests, and I would agree that this is true in a subjective, less fluctuating sense, but it should also be able to be described objectively by the observer. I maintain that emotion and feeling are more general and approximate synonyms for either mood or affect and are probably less scientific descriptors. Emotion is believed by some to refer to feeling states that are accompanied by obvious physiological arousal.

RICHARD KETAI, M.D.
Ann Arbor, Mich.

Neuropsychiatric Symptoms in Hypoglycemia

SIR: As one of the oldest living researchers in the field of neuropsychiatric phenomena in hypoglycemia, I take the liberty of making a few supplementary remarks on the excellent paper "A Psychiatric Study of Patients Referred with a Diagnosis of Hypoglycemia," by Charles V. Ford, M.D., and associates (March 1976 issue).

The simplest method to determine if neurological and psychiatric symptoms are due to hypoglycemia is to feed or, better still, inject intravenously a certain quantity of dextrose. If the symptoms do not promptly disappear they are not due to hypoglycemia.

I have pointed out elsewhere that for many hypoglycemic patients hospitalization is a psychic trauma that tends to temporarily raise their blood sugar levels. In such cases I recommend waiting for a few days after admission before starting observations and serum glucose studies.

JOSEPH WILDER, M.D.
West Hartford, Conn.

Correction

In "Decreased Blood Platelet MAO Activity in Unmedicated Chronic Schizophrenic Patients" by Edward F. Domino, M.D., and Sumathy Sampath Khanna, Ph.D. (March 1976 issue), the units of MAO activity were incorrectly described as μmol/mg protein/hour; this should have read nmol/mg protein/hour. This error was pointed out to us and to Dr. Domino by Ross J. Baldessarini, M.D. Dr. Domino has informed us that the problem resulted from typographical errors on the original manuscript and wishes to apologize for any confusion this may have caused *Journal* readers. The staff wishes to thank Drs. Domino and Baldessarini for correcting this error.

BOOK REVIEWS

Psychotherapy of Schizophrenia, *edited by John G. Gunderson, M.D., and Loren R. Mosher, M.D. New York, N.Y., Jason Aronson, 1975, 433 pp., $17.50.*

In a disorder that is so inherently heterogeneous as the schizophrenic syndrome, it is to be expected that multiple therapies compete for primacy and that their supporters tend to suffer at times from an excess of passion rather than perspective. The somatic therapies, i.e., convulsive and surgical, are attacked and defended violently in an atmosphere that is remarkably devoid of data. Partisan positions continue to be held in the face of contrary evidence. Megavitamin therapy, for example, has not disappeared even though carefully controlled studies failing to show its value have been published. The psychotherapy of schizophrenia has endured many of the same vicissitudes.

Intensive individual work with schizophrenic patients dominated the training centers in American psychiatry before the advent of chlorpromazine. During this period psychotherapy was seen as the preferred if not the only treatment. Students were taught that psychotherapy helped the basic or true problems causing the illness rather than merely reducing symptoms. The initial reaction of psychoanalytically oriented centers to the neuroleptics was hostile and depreciating. It was even argued that these drugs interfered with psychotherapy and should therefore not be used. This antiscientific attitude helped to polarize psychopharmacology from psychotherapy. Today there are only a few colleagues who are genuinely skilled in both treatment modalities.

Gradually, chlorpromazine and other phenothiazines displaced psychotherapy as the major method of treatment. The number of people teaching and learning intensive individual psychotherapy diminished. Institutions shifted to short-term care and reliance on drugs. Psychotherapists tended to retreat to a few centers that carried on the older traditions with a selected patient population. The political climate changed dramatically. This can be best seen in statements about the relative efficacy of pharmacotherapy versus psychotherapy. In the 1950s the drug companies suggested that psychopharmacological agents made it more possible to do psychotherapeutic work with schizophrenic patients. More recently it has been suggested that psychotherapy encourages patients to come back to the clinic and take their medication. As with all emotionally charged debates, the first victim in this controversy has been rationality.

The editors of this volume hope to improve the situation. They have brought together a group of colleagues who are primarily identified with the individual psychotherapy of schizophrenia. Many outstanding therapists are represented in this book. The entire first section is devoted to clinical practice and reviews the major controversies concerning the psychotherapy of schizophrenic patients. Every clinician will find something of value here. The second section is more theoretical in nature and touches upon several different formulations of schizophrenia. The final section deals with research on psychotherapy. Here balance and perspective are brought to bear on the question. The issues are joined scientifically rather than affectively. Evidence is reviewed and evaluated rigorously. The authors attempt to identify what further data would be useful in evaluating the effectiveness of psychotherapy.

As is to be expected in a multiauthored volume, the chapters demonstrate not only a range of viewpoints but a range of quality as well. Nevertheless, the editors have done an excellent job of maintaining a coherent volume in the face of this diversity. The book is an outstanding effort to deal with many of the pertinent issues surrounding the psychotherapy of schizophrenia and can be strongly recommended to anyone interested in the subject.

ROBERT CANCRO, M.D.
Farmington, Conn.

The Psychoanalytic Study of the Child, Vol. 30, *edited by Ruth S. Eissler, Anna Freud, Marianne Kris, and Albert J. Solnit. New Haven, Conn., Yale University Press, 1975, 751 pp., $22.50.*

Entering its fourth decade, the *Psychoanalytic Study of the Child* continues to take a seminal role in developing psychoanalytic theory and practice. Heavily influenced by the Hampstead Child Therapy Clinic, this annual contains 28 generally useful papers on child development, theory, clinical problems, preventive psychiatry, and psychohistory.

A feeling for this volume can be gained from skimming the surface of its contents, beginning with Dorothy Burlingham's list of blind infants' special problems and ending with Stephen Weissman's psychological study of Frederick Douglass. In between are discussions of the congenital absence of sensation, language deficits in children, infant observation, the phallic-narcissistic phase, the origins of awe, ambivalence, the "mirror" dream, childhood memories as contents of schizophrenic hallucinations and delusions, preventive intervention in adolescence, and the impact of surgery on boys.

A number of papers deserve special attention because they are significant contributions. First is the description of a central psychic constellation by Silverman, Rees, and Neubauer. This article nicely clarifies the personality organization of the pre-oedipal child and the appearance of the synthetic function of the ego during the fourth year of life. The authors offer tools for recognizing the enduring foundations of a child's personality by the age of three and a half in the form of characteristic ways of responding to drives, using external resources, and expressing self-esteem.

Burness Moore performs a service by reviewing the concept of narcissism, a long-standing source of confusion in the

literature. He defines narcissim as a positive, libidinal feeling toward the self with parallel and intermingled aggressive feelings. He sees narcissism as the energy interchanging with mental representations in psychoanalytic theory just as energy and matter interchange in the physical world. He endorses Mahler's view that narcissistic disorders result when a mother who had serious problems in her own separation-individuation is not gratified by her own child's individuation. As a consequence, her child incorporates her image, and the child's own self remains an alien, unsatisfying "as-if" object. In a similar vein Berger and Kennedy extend our knowledge of the maternal contributions to learning disorders in children. They found that a mother's lack of pride and pleasure in her child can lead the child to unconsciously comply with the mother's imposed image of backwardness, with resulting personality distortion.

Although addressed to child analysis, the discussion of transference by Sandler, Kennedy, and Tyson stands as a classic for transference manifestations in all forms of psychotherapy. Drawing upon Hampstead Index data, they describe four kinds of transference phenomena. First are the patient's habitual ways of generally relating to people, including the therapist; second are reactions from current relationships that "spill over" into the therapeutic relationship; third are past experiences that are relived during the therapeutic process; and last is the transference neurosis, which is a concentration of distortion within the therapeutic process with consequent diminution in their appearance elsewhere. The authors also wonder how much of the presumed transference neurosis with children actually is a result of the child's license to regress in treatment and discharge regressive wishes that then no longer appear elsewhere.

Another helpful therapeutic clarification is offered by Van Dam, Heinicke, and Shane. They see treatment termination as an extended process, evoking case-specific and phase-appropriate defense mechanisms in response to the loss of the therapist. They suggest a multiple-aspect view during the pretermination phase of therapy that takes into account all of the factors that determine the child's overall functioning in addition to treatment material. They also note that children quickly develop an amnesia for treatment, often remembering the analyst only in demeaning terms.

The most innovative paper is Gilbert Kliman's description of the Cornerstone method, an integration of analytic practice with a nursery school for emotionally disturbed children. Treatment is performed only in the classroom and augmented by the nursery school staff. Kliman's experience stands as a model for the effective psychoeducational treatment of the young child. In a similar way a model for the humanitarian care of surgical patients is offered by Solnit and Priel in their sensitive description of the team treatment of Israeli soldiers with severe burns.

In the social arena, Zinberg draws on current clinical experience and demonstrates that the physical and social settings must be taken into account in the genesis of drug addiction. Motivation and unconscious conflicts leading to drug dependency are important variables but not the direct causes of addicts' deterioration.

The foster care system is indicted by Goldstein, who points out that foster care frequently deprives the child of a family. Among other things he recommends the statutory creation of a "foster child with tenure" by a cutoff period of 12 to 18 months after which the foster relationship is defined as no longer temporary to facilitate adoption of the child by the foster parents.

An evening with this volume will acquaint the reader with a rich resource for further reference and with the value of the *Psychoanalytic Study of the Child* as an annual addition to the psychotherapist's library.

JACK C. WESTMAN, M.D.
Madison, Wis.

Europe's Inner Demons: An Enquiry Inspired by the Great Witch-Hunt, *by Norman Cohn. New York, N.Y., Basic Books, 1975, 292 pp., $12.50.*

The great medieval witch-hunt has long interested modern psychiatrists, partly because the delusional notions underlying it so closely resemble the psychotic ideas we encounter daily. This resemblance has led some psychiatrists, e.g., Zilboorg, to see the witch-hunt as arising primarily from individual psychopathology, an understanding of which, they suggest, can best help us understand the witch craze.

Medievalists, on the other hand, tend to seek explanations of the witch-hunt primarily in political, religious, and ideological history. Therefore, they view the delusions themselves, both individual and group, as secondary. Professor Cohn, the distinguished Chairman of Sussex University's Center of Research in Collective Psychopathology (now the Columbus Center) in England, demonstrates this approach most convincingly in this book. In presenting the definitive account of the various ideological currents—political, social, religious, psychopathological, and even fraudulent—which, coming together, produced the witch-hunt, he also corrects many of the accidental and intentional errors that have so gravely distorted many earlier accounts and appraisals.

The key belief underlying both the medieval witch-hunt and those of Hitler's Germany and McCarthyite America was the belief that, because of their alleged adherence to Evil, certain individuals were so terrible a threat to society that they had to be denied the ordinary protections and procedures of the law. When this occurred and, particularly, when torture became a major method through which such individuals were forced to "confess," the witch-hunt reached its peak. The fear of these "inhuman humans," plus their own "confessions" to the most outlandish and impossible "crimes," led to an abdication of reality testing at the highest social and political levels.

Each of the separate elements leading to the view that some humans are or have become inhuman has a long and complicated history, usually religious in origin, and Cohn delineates them carefully. Accusations of group infanticide, cannibalism, and incest, for example, were brought against second-century Christians by religious adversaries; later, the same accusations were leveled against "heretics" and other opponents by the Christian Church.

When legal protections were removed, the accused became vulnerable to the accusations of both sincere fanatics and mendacious careerists, who enhanced their own power by using torture to obtain the "confessions." These were carefully recorded, creating a corpus of concepts for later inquisitors to "elicit" from their own tortured victims. The repeated reassertion of such unbelievable fantasies can cause them to be believed, particularly in times of stress and especially when backed by the highest authority. This was Hitler's and the witch-hunt's "big lie."
As Cohn points out,

> The origin of the new [sixteenth and seventeenth century] stereotype of the witch lay . . . in the evidence ex-

tracted during the trials themselves. The grain of truth in the evidence lay in the fact that some people really believed themselves to fly at night, and that some women believed themselves to copulate at night with incubi. The rest came from the imagination of certain inquisitors, bishops and magistrates, who used and abused the inquisitorial procedure to obtain all the confirmation they needed. (p. 238)

Really massive witch-hunts occurred only where the concept of witchcraft included the sabbat ["the sacreligious and orgiastic gatherings" of the witches] and where judicial procedure included torture. (p. 254)

Cohn also delineates some of the erroneous notions that have arisen concerning the witch-hunt, such as the false belief that there were indeed conspiratorial political groups against which the hunt was directed. His meticulous research of the sources of this notion, some erroneous and some even fraudulent, is a pleasure to read.

This volume is a fascinating, scholarly, yet easily readable analysis of the many ideological sources of the witch-hunt, among which individual psychopathology is relatively unimportant. It is highly recommended to all interested in the origins and development of the collective myths and fantasies underlying one of Europe's most shameful episodes, one that has reverberated loudly even into our own times.

Hallucinations: Behavior, Experience, and Theory, *edited by R.K. Siegel and L.J. West. New York, N.Y., John Wiley & Sons, 1975, 311 pp., $25.00.*

Hallucinations are strange. Some artists have them, some inventors have them, some musicians have them, and even some schizophrenic persons have them. Now science is about to explain their significance; psychiatry cannot. I am not sure that philosophy can either, although philosophers have tried—Aristotle, Plato, Descartes, Hobbes, Russell, Wittgenstein, and James.

This book is filled with gems, but it is not easy to read. There are many differences in writing styles, models, theories, approaches, content, and context. Personally, I would prefer to experience hallucinations than to read about them.

The subtitle of this book, "Behavior, Experience, and Theory," reflects some of its boundaries. Siegel and West are to be congratulated on assembling such a dedicated group of researchers who know the literature and who are devoted to expanding man's knowledge of his dreams and perceptions, experiences and sensations—the whole gamut of varieties of levels of consciousness.

If I were to relive my professional life and training, I would insist on at least a full year in philosophy at some place like the Institute of Philosophy in Louvain, Belgium. This book reinforces such dreams.

Some of the authors, in particular Fischer, Sarbin, Juhasz, and West, deeply dissect our APA-approved definitions of perception, hallucination, pseudo-hallucination, hypnagogic and hypnopompic hallucination, reality, and sensation. In certain ways the book is like an encyclopedia of physiology or pharmacology. It is attractively printed, and the art by Sheridan and Yando is excellent.

The book is scientific in the best sense, i.e., it is not pompous, admits the limitation of knowledge about hallucinations, and yet offers a myriad of information, theories, facts, and hopes for the future. One of the authors predicts that it will take 100 years to really understand hallucinations. Other authors advise caution to us clinicians. Hallucinations may be transpersonal; it may take the psychiatrist as well as the patient to complete the act of diagnosing someone as hallucinating. Therein lies a warning:

Hallucinations are too important to be left entirely to clinical psychiatrists. . . . The average psychiatrist is confronted all too often by uncreative hallucinating patients who are stuck with conflict and unable to follow that "vast and painful initiation rite" (Bateson, 1972) [(1)], the path from agony to ecstasy: the process of disintegration and rebirth through symbolic experiences. (p. 233)

At least in the popular culture, hallucinations now can have a positive valuation, e.g., Laing, Castaneda, Fischer, Scheff, Goffman, Mutwa, and even Jung!

Intermediate cases between dreams and hallucinations can be found among the so-called hypnagogic [sleep-inducing] and hypnopompic [sleep-terminating] hallucinations. (p. 263)

The distinction between sensations and perceptions is one of the most popular and yet one of the most obscure distinctions in psychology. (p. 265)

This book will be avidly read by certain researchers and for Lent by others. I particularly recommend it to clinicians for bedtime reading.

The Experience of Introversion: An Integration of Phenomenological, Empirical, and Jungian Approaches, *by Kenneth Joel Shapiro and Irving E. Alexander. Durham, N.C., Duke University Press, 1975, 177 pp., $8.75.*

The authors have set out to "confirm a debt" to Jung as "one of the most sensitive observers of the subtle but pervasive individual differences that constitute human personality." The focus is on Jung's seminal, intuitive insight into the typology of personality and the concept of the introvertive personality. Shapiro and Alexander examine a proposed integrated empirical methodology and an experiential phenomenological formulation.

From their Thematic Apperception Test research with a group of undergraduate students, the authors conclude that the concept of psychological distance is probably central to all considerations of introversion and extroversion. The sense of distance between people leads to their discussion of the "introvert's people problem." The way in which the introvert lives and reflects experience results in a reversal of what is usually public and what is usually private. The introvert's life experience is a "peculiarly private affair since it is felt to be unshared in the moment." In compensation, the

introvert attempts to share his private thoughts and feelings, but, because this is asserted as a product intimately related to his own self-development, it has a disengaging effect. The feeling of exclusive possession, density, and opacity of the introvert's transformed world and the mediated nature of his experience, according to the authors, make the introvert's world a cumbersome burden in an interpersonal setting. The sense of interpersonal distance remains omnipresent.

(Jung said he used his typological work to understand the differences between himself and Freud: he discovered that he was an introverted, intuitive, thinking type; Freud was apparently an extroverted, sensation, thinking type. They therefore saw psychological and reality phenomena differently, as different truths.)

Shapiro and Alexander say that Jung was not only rescuing the introvert but perhaps recasting and elevating him above the extrovert. The evidence for this is inconclusive, but it seems clear that Jung created a new awareness of introversion as a normal human attitude reflected in particular behavior. Although he did not lead an introversion liberation movement, Jung did partially rescue ordinary introverts from the early Freudian interpretation as "a turning of libido from the object to the self-yielding fantasy, a kind of narcissistic cathexis of one's wish-fulfilling instincts . . . a pathological adjustment."

Citing Jung's Tavistock lectures of 1935, Shapiro and Alexander state that Jung reverted to a notion that introversion was pathological: "What is left of introversion, if anything, is indistinguishable from Jung's notion of neuroticism." This is not consistent, however, with Jung's concept of the normality of attitudes and functions except when they are extremely dominant in consciousness or disturbed and projected from the unconscious. Because Jung was using a different nomenclature in the Tavistock lectures, the authors have identified one of the many paradoxes and contradictions in Jung's writings.

This intellectual book is somewhat difficult to follow because of the writing style, which moves from formulations of great precision to rhetorical ambiguity. An example follows:

> In a way, with his I/E [introvert/extrovert] distinction, what Jung has done with respect to some fundamental problems in philosophy and psychology is facile; and, in a way, it is elegant. From one point of view, he has begged the philosophical question or dilemma of what is the proper and orginal grounding of reality, the knower or the known, the world-creator or world. He has also begged the psychological question as to the sorting out of the respective roles of the subjective and the objective in an individual's consciousness. His "answer" is the clear equivocation: There are two classes of individuals, the one oriented to the subject in consciousness, the other to the object. But from another point of view, what Jung has perpetrated is a dazzling coup in the history of ideas.

The book is recommended to research psychologists and students of typology. However, the rich humanness of the introverted experience can be found in Jung's *Psychological Types* (1), which the authors state is "one of the most compelling descriptions of people in the personality literature, or any other literature. One wonders why it is not read more."

The authors conclude, "We recognize immediately, without reflection, introvertedness. We know its appearance, but we want to know how to understand it, how to say what it is, and we want to know what it is to live it." Maybe this can be found only by being an introvert or by living with one—in analysis or, better still, in the works of artists and writers, especially poets, dramatists, and novelists.

Predictability in Psychopharmacology: Preclinical and Clinical Correlations, *edited by Abraham Sudilovsky, M.D., Samuel Gershon, M.D., and Bernard Beer, Ph.D. New York, N.Y., Raven Press, 1975, 283 pp., $22.50.*

Development of most prototypic psychotherapeutic drugs is characterized by a strong element of empiricism. The goal of science is to be able to predict. The contrast between the way new psychotherapeutic drugs are found and the way they should be discovered according to scientific thought has put most psychopharmacologists in a bind. This collection of papers relates to the subject of improving predictability. As is usually the case with such collections, topics are covered scantily, and many of the papers have appeared elsewhere.

One of the major problems in the clinical study of drugs is the accuracy of diagnosis. One long chapter in this book recounts the development and present state of research diagnostic criteria. Another chapter tries to make some sense out of depressive disorders. One supposes that it would be a step forward if everyone would at least clearly define the diagnostic terms they use. Two chapters deal with prediction of drug effects by using the EEG profile. After a decade of work on this area, only a couple of laboratories actively pursue this approach; independent vertification of the procedures is therefore lacking.

Two chapters on antianxiety drugs trot out the old notions that these drugs can be detected by the various impairments they produce, by subjective reports of relief of anxiety, and by changes in galvanic skin response. The animal separation model of depression is given a plug, but this analogue of so-called anaclitic depression in humans has not been proven to be universally predictable for other kinds of antidepressant treatment. The idea of rating animal behavior in the same way we rate human behavior and characterizing drugs by their behavioral profile is hardly new, but techniques have been further refined. Some techniques may be like the relationship between the barometer and the weather: the barometer tells you what kind of weather is present.

Long-acting neuroleptics can be tested by using the conditioned avoidance paradigm, perhaps the first of the major pharmacological screening tests for antipsychotic drugs. A more exciting and novel but highly laborious technique for screening antipsychotic drugs is to measure single-cell dopaminergic neuron firing. Antipsychotic drugs reverse amphetamine-induced depression of firing.

One of the chapters in this book speculates on the possible "endogenous psychotogen" basis for schizophrenia and suggests that a selective antagonist of dimethyltryptamine might be a valuable antipsychotic drug. This speculation is interesting but a bit farfetched.

One may be able to learn something about the nature of new compounds by the way they interact with receptors.

Benzodiazepines displace strychnine from glycine receptors, but such binding is probably less related to antianxiety than to muscle relaxant effects. Phenothiazines and tricyclics bind to muscarinic receptors, but these are hardly related to their antipsychotic effects. Still, like the use of single-cell firing rates, receptor interactions are potentially more specific screening tests that any we have had before.

This volume would be of most use to those who have the job of trying to screen new compounds for potential therapeutic usefulness, primarily at the preclinical level. It is doubtful that the clinical evaluation of such compounds will be much changed by any ideas put forth in this book.

LEO E. HOLLISTER, M.D.
Palo Alto, Calif.

The Inability To Mourn: Principles of Collective Behavior, *by Alexander and Margarete Mitscherlich; translated by Beverley R. Placzek. New York, N.Y., Grove Press (Random House, distributor), 1975, 308 pp., $12.50.*

This husband-wife team of German psychoanalysts examines "certain psychological processes which, taking place within large groups, result in the spread of either freedom or unfreedom of thought and insight." Their sociopsychological analysis in the first chapter attempts to deal with the illusions in German thought and behavior before, during, and after the Nazi experience. Having luxuriated in the world-redeeming dreams of greatness and in the idealization of Hitler as the Führer, Germans reacted to their defeat in World War II with effective but psychologically and politically expensive defenses that obviated mass melancholia by derealization of the past, identification with the victors, and manic efforts at physical and economic reconstruction. Three brief case vignettes of individuals with various political attitudes illustrate these psychological processes.

The remaining chapters discuss the broader issues of the subtitle, "Principles of Collective Behavior," from the psychoanalytic point of view. Man's adaptability to civilization is critically challenged by the increasingly complex conditions of our historical evolution. Our drives and needs, the ever present readiness for aggression, are inadequately controlled by the conservative values of traditional moralities, with their taboos and prejudices, which are made obsolete by the transformation of our environment through progressive industrialization, scientific permeation, and all-encompassing administrative machinery. Recent history has altered and weakened the roles of parental models and thereby created identification difficulties for adolescents, resulting in prolongation of adolescence. Clinical studies have suggested rather precisely age-related effects on growing youngsters of the absence of fathers during World War II and the delayed postwar recognition of "how deeply Germany had been compromised."

Several chapters consider tolerance (belatedly proclaimed and hesitatingly practiced), the social and personal ego, and the changing patterns of authority. Finally, the authors discuss the consequences of our historic evolution: affluence and the problem of renunciation; "traceless work," which erodes self-esteem and creates aggressive-depressive tensions; and increasing administration by specialists, leading to fraternal controls superseding the paternal and aggravating the problems of envy.

The book is a collection of separate essays. It is noted in the German edition (1) that, although the first and last chapters were written specifically for this book, the others are compositions prepared for the radio or for diverse publications. Thus the focus of the book—whether the authors address themselves to the expert, the student, or the lay reader—is not clear. The attempt to relate individual psychology of the unconscious to the sociology of collective behavior complicates the issues of readership and level of discourse. From the point of view of the authors' psychoanalytic orientation, the volume also suffers from a dichotomy of emphasis: the first chapter reflects a classical orientation heavily based on Freud's drive theory, but the later discussions reflect and emphasize the more recent developments and orientation of ego psychology. The Mitscherliches appear very well acquainted with the psychoanalytic literature in English.

The translation is faithful and competent. The index, however, is not improved by adding "Dresden bombing" and omitting "depression" in this work on mourning.

The original German publication was on the German best-seller list for about a year in 1967 and sold more than 100,000 hardcover copies, but it had little impact in the United States. Nevertheless, as Robert Jay Lifton points out in his preface to this edition, the Mitscherliches' discussion is most timely for post-Viet Nam and post-Nixon America. I particularly recommend the first chapter to all psychiatrists.

Medical Aspects of Human Sexuality: 750 Questions Answered by 500 Authorities, *compiled by Harold I. Lief, M.D. Baltimore, Md., Williams & Wilkins Co., 1975, 314 pp., $14.00.*

In 1967 Dr. Harold Lief helped establish the new journal *Medical Aspects of Human Sexuality*. Since then this periodical has fulfilled its promise of providing information and critical discussion on sexual topics for medical practitioners. This book consists of questions and answers reprinted from the journal.

The strengths and weaknesses of this volume are a function of its format. It is meant to be practical and oriented toward the practitioner's office rather than the classroom or the scientific meeting. To their credit, the respondents have obviously taken pains to write simple, lucid prose. Because the individuals answering the questions have had different types of training, the reader is provided with a perspective on the similarities and differences among medical practitioners, Ph.D.s in many fields, researchers, and clinicians. Of particular value is the fact that the personalities of the authorities are often revealed as they would be in an informal seminar situation. Although some of the replies are marvelously compressed minilectures, some of necessity suffer because the topic defies the structural requirement of brevity. One frequently but not invariably successful method used by Dr. Lief to avoid oversimplification was to include more than one answer to the same question by authorities of differing views.

Reflecting the interests of medical practitioners who wrote for the journal between 1967 and 1975, the book omits areas

that will perhaps receive more attention in the future. Cancer, facial injuries, renal dialysis, and loss of body parts other than sexual organs could have been profitably discussed. The section on pharmacology is interesting but brief; future dialogue between practitioners and their consultants will no doubt emphasize in greater detail the numerous drugs commonly used that may influence erotic behavior.

Some questions in this book would not have been asked by psychiatrists, although the entire volume should prove useful reading for medical students and general practitioners. However, only psychiatrists who specialize in sexual behavior will know the answers to the majority of the questions. Large parts of the volume will therefore be of interest. In addition, the reader will enjoy meeting experts he might not have been privileged to know. On the whole, this is an interesting compilation and one hopes it is the first in a series.

Psychiatric Illness in Adolescence: Its Psychotherapy and Prognosis, *by M.T. Haslam, M.A., M.D., D.P.M. London, England, Butterworths, 1975, 118 pp., £5.00.*

This very short book convincingly validates theories about the origins of adolescent emotional illness that have been talked and written about for decades. After a tedious but thorough review of the literature relating to early childhood deprivation, the author describes his own research study and minutely examines its statistical findings.

Haslam matched 50 consecutive admissions to a psychiatric unit against the same number of adolescents of similar age and sex who were seen at a casualty unit and had no psychiatric symptoms. Comprehensive questionnaires were administered to both groups. The important historical facts in the questionnaire centered around separation, traumatic experiences other than separation, total adequate relationships (TAR), and mutual understanding response (MUR), an unusual category that rated the degree of difference between the parents' and the adolescents' views of the nature of their relationship early in the adolescent's life.

As might be expected, the psychiatric patient group had a more deprived or traumatic history than the control group, but there were some surprises in the correlations between diagnosis and age at separation and length of separation. For example, the author found that early separation (birth to 18 months) was correlated positively with the development of anxiety symptoms in adolescence, but that separation later in childhood (18 months to 4 years) occurred most frequently in adolescents who developed psychotic symptoms. Relationships between TAR and diagnosis and the prevalence of a low MUR in the psychiatric patient group were also of particular interest.

In addition to the original study, Dr. Haslam conducted 2–5-year follow-up studies on 20 of the 50 psychiatric patients and came to some interesting conclusions in regard to prognosis. For instance, he states, "Bad mothering and separation at a critical age may . . . lower I.Q. and this in turn leads to a poor prognosis."

It was disappointing to learn that what the author terms "relationship therapy" proved to be more effective than no treatment only for patients diagnosed as having adolescent personality disorder—not for patients in other diagnostic categories, such as schizophrenia, depression, and anxiety.

This book makes valuable reading because of its confirmation of the important influence of childhood experiences and relationships on adolescent adjustment. The research material is presented in such detail that the reader must be well versed in statistical analysis to understand it all, but the author's summaries are clear and concise, so the conclusions of the studies are easily grasped. Everyone interested in the dynamics of emotional illness will profit from reading this report.

GRAHAM B. BLAINE, JR., M.D.
Cambridge, Mass.

Safeguarding Psychiatric Privacy: Computer Systems and Their Uses, *edited by Eugene M. Laska, Ph.D., and Rheta Bank, M.A. New York, N.Y., Wiley Biomedical (John Wiley & Sons), 1976, 445 pp., $22.00.*

From every side, the privacy of citizens is abridged as the nation becomes more centralized and more authoritarian. With our present emphasis on community mental health centers and third-party payment for health services, our need to protect the privacy of the consulting room increases. Conflicts between the patient's right to privacy and society's alleged need to protect its citizens and monitor its expenditures become more common. Central to this controversy is the issue of medical records—their content, control, and availability, not only for the immediate needs of the physician-patient interaction, but for Professional Standards Review Organization (PSRO) and utilization reviews, accountability, and funding.

The issue has surfaced in two ways in psychiatric practice: in individual legal challenges to the confidentiality of psychiatric records and in the growing use of digital computers to record, maintain, and analyze psychiatric records. *Safeguarding Psychiatric Privacy*, a collection of reports by a diverse group of writers, is an excellent introduction to two aspects of the problem: the technical issues of data collection using the multistate information system (MSIS) and the legal and political issues concerning access to records.

The major thrust of the volume is a description of the development and present status of this widely used record system, as developed at Rockland State Hospital in Orangeburg, N.Y. Case forms and sample outputs are described and portrayed and their many uses suggested. The text is designed for the medical reader rather than for the computer or engineering specialist. The flexibility of the MSIS is seen in its interesting applications: to administrative decision making and program evaluation at a Connecticut mental health center; to diagnosis and patient monitoring; to the development of the problem-oriented record for psychiatrists; and to setting up new mental health delivery systems in Israel and in Indonesia. The system described in these chapters is substantially more mature and sophisticated than the system described in 1968 (1) and even the one described in 1974 (2).

This volume is particularly stimulating in its second, less technical section, which is devoted to the issue of confidentiality. If records are computerized and data banks are accessible across the nation (and indeed the world) by computer cross-talk, how can we protect the confidentiality of psychiatric records? The authors of these chapters exclude the likelihood of an extension of the medical ethical code to computer technicians as well as a voluntary code of confidentiality. They suggest legal protection of access to data banks by appropriate federal laws. They also appeal to the

World Health Organization to develop a model international law.

They see the issue of confidentiality as transcending national boundaries. Their plea is idealistic in these times of global power struggles and the reawakening of the cold war. They also suggest more local regulation because they hesitate to depend on federal regulation alone. Passage of the Federal Privacy Act of 1975 (which went into effect on September 1, 1975) is seen as a first step in this needed development. Articles by Senator Barry Goldwater of Arizona and Representative E.I. Koch of New York provide an interesting background to this legislation.

The volume is an introduction to the uses of MSIS and to the problem of privacy of medical records. As psychiatrists participate in the progressive nationalization of medical practice, the issues in this volume will become more compelling. Laska and Bank have done psychiatry a service by alerting us to these important issues and by providing thoughtful postures for clinicians, politicians, and our legal colleagues—to whom this volume is highly recommended.

Forensic Psychiatry: A Practical Guide for Lawyers and Psychiatrists, *by Robert L. Sadoff, M.D. Springfield, Ill., Charles C Thomas, 1975, 245 pp., $14.50.*

The word "practical" in the subtitle of this book is most apropos. This is a book for working professionals. Dr. Sadoff addresses both psychiatrists and lawyers on the subject of what each should expect from the other in the many areas in which their professions converge. The attorney will learn, for example, the benefits of the psychiatric expert's knowing as much as possible rather than his or her being embarrassed under cross-examination, the medical rights of the patient who is his or her client, and the medical responsibilities of the psychiatrist as a consultant in the courtroom. It seems to me that much of the practical material in this work is directed toward the psychiatrist who is just getting into legal matters by one who has had experience. There is a great deal of useful advice on how to make a forensic report, how to prepare expert psychiatric testimony, how to use the results and interpretations of laboratory and psychological tests in court, and even how to dress for a hearing or trial.

Dr. Sadoff recognizes basic differences between the orientation of the professions of law and psychiatry. The aim of law is to control behavior; the goal of psychiatry is to understand it. The main intent of the book seems to be to enhance service to the court, the individuals, and the community through interdisciplinary cooperation and compromise.

One problem raised by Dr. Sadoff is that in both criminal and civil cases a psychiatrist is retained by the prosecution or the defense; there may well be bias in the psychiatrist's not being more neutrally appointed by the court. The function of the psychiatrist, he emphasizes, is to be a consultant and educator to the court; it remains with the judge and/or jury to assess guilt.

Chapters such as those on the juvenile and criminal law, sexual offenders, alcohol and drugs, mental competency, domestic relations, and commitment show the wide range of issues presented in this book. Sample cases highlight tendencies in each kind of case as well as unique aspects that dramatize the points being made.

University training is available in the field of forensic psychiatry. The author points out that only a naïve psychiatrist could plan to avoid court proceedings. The psychiatrist may well become involved with the law in two areas of malpractice: he or she may be an expert witness in a case involving another doctor or he or she may be a defendant in proceedings. In either instance, the psychiatrist must be prepared with the knowledge of the legal factors leading to malpractice, the relevant particulars of the case, and appropriate court presentation.

The book seems more directly addressed to psychiatrists than to attorneys. It smooths the way for more effective communication between two disciplines that increasingly must understand each other.

MYRON H. MARSHALL, M.D.
Buffalo, N.Y.

Childhood in China, *edited by William Kessen. New Haven, Conn., Yale University Press, 1975, 234 pp., $12.50; $3.95 (paper).*

Anyone concerned with child development will find this report of a visit of 13 American specialists in childhood to the People's Republic of China a necessary book. The various authors offer a thoughtful, ranging review of child rearing, family relationships, the status of schools, and the development of child health services. The combination of well-written text and arresting photographs offers a particularly detailed, vivid look into what is going on in the fascinating country of mainland China.

The group of distinguished visitors included psychologists, sociologists, a nursery school teacher, and a pediatrician who were invited by the Chinese government to observe a considerable number of nursery schools, kindergartens, primary schools, middle schools, and boarding schools. The group visited hospitals, health clinics, and the homes of Chinese families. Their many and varied observations have been collated into this detailed, evocative report on the status of childhood in China. Photographs of children in natural settings—playing, dancing, learning, interacting with their families—greatly enhance the value of this indispensable guide to the status of both children and families in the People's Republic of China.

Differences between American child-rearing practices and those in China are contrasted through anecdotes culled from many settings. The visitors observed that Chinese children were

> far less restless, less intense in their motor actions, and displayed less crying and whining than American children in similar situations. We were constantly struck by the quiet, gentle and controlled manner of Chinese children. All of us agreed that the gentleness and control of the children bore a resemblance to the gentleness and control of the teachers.

Repeatedly, the observers note with considerable awe that Chinese children were well mannered yet spontaneous, interested in the observers yet quite comfortable and able to continue with their activities. Children accepted observers as natural, pleasant additions rather than stimuli for excitement, disorganization, or regression.

The authors note that typical school lessons in China include moral lessons, lessons of cooperation rather than competition. In their descriptions the observers note that Chinese children are taught through books, stories, and recitations to share with others, to give another child a place in the line, and to cooperate with other children. Such descriptions call to mind the contrary observations made of the American competition-independence-disengagement ethic described by Philip Slater (1).

The observers note that "nowhere is there any evidence of inclusion of an activity in the program simply for its own sake." Rather, each activity is made to fit in with the moral development of the child and the needs of the community and the society. The observers emphasize the seriousness of the lessons Chinese children are given in their classrooms and compare them with the American educational system's concern with "nonsense like the 'Eency-Beency Spider.' " Standards were uniformly high, and children were taught by positive examples and gentle repetition. The teachers were said "to consider individual criticism and punishment to be undesirable methods of improving performance."

The observers comment on the prodigious ability of the children for memorization and accurate reproduction of dances and pictures as well as their effectiveness in acting out long dramatic scenes from plays. They state, "Everything we saw was on cue, and no one except the children of foreign diplomats missed a cue."

The observers remark repeatedly on the absence of fighting, pushing, and other disruptive behavior on the part of children. Similarly, they note the uniformly supportive and positive attitude of teachers and other staff toward their children and conclude that "teachers and staff members established an atmosphere of warmth, approval and perhaps most important, a confident expectation that each child would behave himself appropriately and succeed at the task at hand." This general atmosphere of approval is said to derive from the fact that Chinese teachers believe in what they are doing and in the future of the children whom they teach. The authors note that before the advent of Maoist China "teachers were said to have been content to care for the children and to play with them. Now they teach because they are involved in developing children who will work hard and be useful to themselves and their society."

These acute observations and comments by a group of observant, sophisticated American child development specialists merit our serious attention. They cannot be dismissed with such statements as that of a colleague with whom I discussed the book, who asked, "But are those children happy?" Perhaps such a comment reveals assumptions about our own society that a reading of this report will challenge. It is difficult to frame serious criticisms—other than political ones—of a child development system that seems to be working so well. It may be more realistic to ask what we can learn from the child development and educational practices of a country involved in a gigantic and seemingly humane experiment in child rearing.

This is a landmark book that should be studied by everyone involved in child development. The lessons in it are clear to anyone who works with children and deserve to be integrated with our own philosophy, or lack of philosophy, in regard to the best ways to educate children to be participants in a healthy, democratic society.

Mental Health: New York Law and Practice, Vols. 1 and 2, *by Jack Zusman, M.D., and William A. Carnahan. New York, N.Y., Matthew Bender, 1975, unnumbered pages, no price listed.*

These two volumes provide the basis for an exploration, analysis, and evaluation of mental health jurisprudence from both theoretical and practical perspectives. The collected experiences of forensic psychiatrists support the assumption that neither lawyers nor judges are familiar with the mental health system. Mental health professionals have therefore been relied on to circumvent the difficulties of administering the jurisprudence of the nonrational, the irrational, and, on occasion, the absurd. As the authors point out, "As a first step in dispelling interdisciplinary ignorance, misunderstandings, and animosities, this book was written."

These volumes attempt an exhaustive exposition of New York's mental health jurisprudence; an authoritative analysis of mental health and legal issues in administrative, civil, and criminal law areas; and a balanced critique of the mental health system from the vantage point of participants in this system. These volumes do not represent a theoretical critique of the mental health system or a polemical assault on the role of institutional psychiatry in legal settings. Although ostensibly written for attorneys and jurists who practice within the mental health system, they represent a fine addition to the forensic psychiatry literature and a model for similar treatises in other jurisdictions.

Legal Issues in Psychiatric Care, *by Laurence R. Tancredi, M.D., J.D., Julian Lieb, M.B., B.Ch., and Andrew E. Slaby, M.D., M.P.H. Hagerstown, Md., Harper & Row Medical Department, 1975, 160 pp., $10.75 (paper).*

According to the authors,

> [This book] was written for use as a textbook for students in all areas of mental health—psychiatrists, nurses, psychiatric aides and social workers, and psychologists, as well as general practitioners and family specialists. Law students and lawyers with a special interest in these issues should find the information and discussions presented here to be of particular value. When psychiatric medicolegal issues arise in medical offices or mental health clinics, a clinician may reach for this book and find ready guidelines without a morass of legal jargon.

Neither the content nor the presentation of this book can be commended. Perhaps the language became awkward and the substance dilute in the attempt to meet everyone's

needs, but I prefer standard legal jargon to such statements as, "Law has been constructed to prevent and account for injuries that are incurred through direct intentional acts or through negligent conduct . . . [whereas psychiatry deals with] the way behavior manifests itself."

The book does not seem to have been checked for internal consistency. For example, we are told on page 14 that "epileptics also are often subject to involuntary commitment" and then advised on page 47 that "with the advent of drugs that effectively control the seizures of epilepsy, the epileptic is rarely hospitalized through involuntary commitment."

The authors' negative claims for psychiatry would qualify them to write for the Scientologists, but their one positive claim is equally dubious, i.e., that there is some valid illustration of "psychiatry's unique position in helping women, blacks and Puerto Ricans." In a chapter titled "Definitional Problems in Psychiatry" they graciously indicate that they will "in all instances take the rather traditional approach that there is indeed something called mental illness."

In summary, this ambitious attempt lacks the substance for a text and the balance and scope for a guide.

Psychoactive Drugs and Social Judgment: Theory and Research, *edited by Kenneth R. Hammond and C.R.B. Joyce. New York, N.Y., Wiley-Interscience (John Wiley & Sons), 1975, 266 pp., no price listed.*

That psychoactive drugs may produce behavioral toxicity in addition to their therapeutic effects was pointed out by Jonathan Cole and others years ago, but our grasp of this area remains shaky.

The editors of this book present a body of research that attempts to bring the evaluation of the toxic effects of psychoactive drugs on social judgment into the experimental laboratory. The basic question for all such studies is whether the experimental model used is a convincing analogue of social judgment and has been validated against criterion ratings of social judgment in appropriate reference groups. Unfortunately, the primary task used in these investigations is neither convincing nor validated. It consists of a procedure through which the subject is exposed to three numbers and then asked to guess a fourth number. After each trial the subject is informed of the correct answer. The subject has to induce the proper rule.

In one procedure, only one of the cues is relevant to the target quantity. In a second, all three cues are relevant to the target quantity and must be combined mentally by the subject.

This does not strike me as a valid experimental model of real-life judgmental processes. The measure concerns accuracy in partly informed guessing of the size of a number. Most social judgmental processes do not involve making a guess concerning quantity but making a guess concerning the truth of a propositional statement or argument.

We may have to estimate a man's IQ by the number of books in his library in combination with the correctness of his English. It is far more likely, however, that we will try to decide whether to move across town, marry, or smile politely. Presumably these decisions can be placed in a propositional framework, e.g., "true or false: entering this new business is likely to increase my income eventually, after an initial dip."

A further drawback to the studies is that no systematic attempt is made to dissect out the variables that might affect social judgment adversely, e.g., is the patient sleepy, inattentive, motivated, "parkinsonized," etc.? Also, the studies suffer from very small samples and a considerable use of retrospective data analysis rather than hypothesis testing.

Some of the studies are naturalistic. Patients are assigned to different drugs by clinical process rather than randomly. These analyses are interpreted in terms of drug effect rather than the possible confounding effects of natural selection. This sort of elementary confusion does not belong in a book of model analyses.

Finally, with regard to the suitability of patient populations, there are studies on acute and chronic schizophrenic patients. One would think that if you are looking for psychotoxic effects on social judgment, the key patient group would be schizophrenic outpatients in remission who are being maintained on medication.

To sum up, this is a disappointing book about an important topic.

DONALD F. KLEIN, M.D.
Glen Oaks, N.Y.

Treatment Settings in Psychiatry: A Comparative Study, *by John B. Copas, B.Sc., Ph.D., Michael Fryer, B.Sc., and Ashley Robin, M.D., D.P.M. London, England, Henry Kimpton (New York, N.Y., British Book Centre, distributor), 1976, 103 pp., $9.50 (paper).*

This careful study examines treatment outcomes for 98 matched patient pairs seen in two inpatient units in Great Britain—a large mental hospital and the psychiatric unit of a district general hospital. The reader is treated to that scarce phenomenon in our field, a well-conceived, methodologically tight, statistically detailed prospective study of demographic and outcome variables that attempts to discover differences and relative superiorities between the general hospital and the large psychiatric hospital as treatment settings. The two hospitals compared, each of which is in the county borough of Southend, are the Rochford General Hospital and the Runwell (Psychiatric) Hospital.

The questions examined by this British study are relevant to treatment planning in the United States, given the large number of psychiatric units opening each year in community general hospitals. Although there is no federal plan for the United States to close public mental hospitals (as the 1971 policy of the British Department of Health and Social Security apparently proposes), the thrust toward "deinstitutionalization" in the United States makes timely an attempt to evaluate the relative therapeutic effectiveness of a psychiatric unit in a community general hospital.

The aim of the authors' project was to compare two inpatient settings with regard to treatment outcome by studying matched patient pairs on a large number of outcome variables using the Wing Present State Examination. Before elaborating their study, the authors describe the community and services of Southend and the two hospitals evaluated. They then present a careful analysis of demographic and diagnostic data for the 98 patient pairs; they call these data "input factors." They then attempt to demonstrate that there was no significant difference between patients referred to each of the two hospitals. Results of treatment are examined in terms of "output factors," i.e., patients were eval-

uated at admission, one month after admission or at discharge, and six months after discharge. Social workers obtained data at similar time frames from the patients' families.

In view of this detailed build-up and the elegant statistical methods and justifications used, the reader is disappointed to learn that there were no major differences between the two groups of patients on any of the treatment variables, although, happily, patients in each setting showed rather marked improvement in symptoms after one month. The authors describe only minor differences in treatment approaches, e.g., Runwell patients tended to remain inpatients longer, and Rochford patients were treated in day programs for equal lengths of time.

The authors acknowledge that they cannot generalize from their findings about the relative effectiveness of the two types of settings per se, but they conclude that there is suggestive evidence that many patients treated in psychiatric hospitals could be treated equally well in psychiatric units of general hospitals. This conclusion seems reasonable, but it is based on an assumption of no initial difference between the patients at admission to each of the units. I believe that this crucial assumption is not supported by their data, even though they interpret them in this way; this one flaw in their study is, unfortunately, a major one. They found that the diagnoses for patients assigned to each hospital were the same for 7 of 11 categories. However, Rochford patients showed greater anxiety and depersonalization and less disturbance of motor behavior. In addition, relationships were less satisfactory for Runwell patients: 13% of them lived alone before admission, compared with none of the Rochford patients. Runwell patients had been unemployed for at least six months more often than Rochford patients, and they had a higher incidence of suicidal risk and previous self-injury.

According to these input factors, it seems to me that one of the groups was indeed more disturbed than the other and, therefore, that inferences based on assumptions of similarity cannot be supported. In an example of gross carelessness uncharacteristic of the rest of their study, the authors ascribe more social isolation to the Rochford patients, but their data demonstrate that the opposite is true (p. 75). Thus, in terms of prognostic criteria, the Runwell patients seem to have been more severely impaired on admission than Rochford patients, findings quite consistent with the impression that patients admitted to psychiatric wards of state hospitals are more profoundly disturbed than those admitted to psychiatric wards of general hospitals. The authors would do well to deal directly with these differences between their two experimental groups rather than blurring them through a wish to find the samples prognostically identical.

Belmont, Mass.

Changing Patterns of Psychiatric Care, *by Bernard L. Bloom. New York, N.Y., Human Sciences Press (Behavioral Publications), 1975, 354 pp., $15.95.*

Critical assessment of mental health care delivery systems continues to be a timely and relevant pursuit. This text describes a social analysis and epidemiological study of psychiatric care in a single catchment area of 120,000 people during the decade 1960–1970. Census tract and inpatient questionnaire data were scrutinized for findings that have implications for mental health programming and preventive psychiatry approaches. The methodology used requires acceptance of the basic assumption that measures of treated incidence in a population bear some positive relationship to the true incidence of all treated and untreated disorders in the same population.

This book, organized into four parts, compares the data gathered in 1960 with those for 1970 from various perspectives. The text has many pages of figures and tables, and although the style is sometimes dull and repetitious, a careful reading reveals startling findings.

In both 1960 and 1970 more than two-thirds of all psychiatric hospitalizations were in private facilities, in which lengths of stay were shorter than in public facilities for every diagnostic group regardless of patient age, sex, or ethnic group. Thirty-three percent of all psychiatric admissions in 1960 were for psychoneuroses; in 1970 this figure was 52%. The number of admissions also increased during the decade (2.73 per 1,000 in 1960 versus 4.81 per 1,000 in 1970), but the percent of diagnoses of functional psychosis was stable, and the number of admissions for organic brain syndrome markedly decreased. Much of the increased admission rate was due to the hospitalization of more people under 21 years old for nonorganic, nonpsychotic disorders.

There was an increase in the number of inpatient beds and a dramatic proliferation of outpatient services during the decade. However, this study indicates that the expansion took place in an uncoordinated fashion. The increase in number and diversity of outpatient programs did not lead to a decrease in inpatient use. In fact, the majority of first inpatient admissions in 1970 were neither screened nor treated first as outpatients.

Cluster analysis of 35 variables used in this study separated out three specific cluster groups: socioeconomic affluence, social disequilibrium, and young marrieds. The three cluster configurations included more than 90% of the communality identified for both 1960 and 1970 census data.

Social class per se was not found to be convincingly associated with treatment rates. Marital disruption in the social disequilibrium cluster was the most striking individual and census tract correlate of patienthood. High frequency of low-level occupation and a greater percent of minority ethnic group individuals distinguished the patient group from the general population, but educational level did not.

The author scrutinizes his findings closely for identifiable stresses to lend support to the social causation hypothesis. Marital disruption, social isolation, and minority status are identified as highly significant stresses. Could preventive psychiatry approaches targeted specifically for these situations lead to a decrease in psychopathology?

Mental health care delivery programs in this community changed so significantly during the decade of study that they are reported to be qualitatively different. However, there is little evidence of cooperation in program planning and implementation between private and public sectors. Although high-risk neighborhoods and individual social situations are identifiable, too little preventive psychiatry has taken place. The author concludes that there is much that is not comprehensive about mental health care in this catchment area. During this decade of increasing funding and personnel effort, there has been little evidence of impact on incidence, prevalence, or severity of psychiatric disability in the community served.

This volume is not a polemic. It is a carefully detailed and thorough study. The author does not extend his comments beyond the limits of his data. Repetition of projects such as this should help us to identify more accurately the results of

community psychiatry programs and will require us to focus on the kinds of changes needed to improve outcome.

Lexington, Ky.

The Best Years of Your Life: A Guide to the Art and Science of Aging, *by Leopold Bellak, M.D. New York, N.Y., Atheneum, 1975, 288 pp., $10.00.*

The nineteenth century found the United States in the midst of promise and progress. The standard of living had increased, but epidemics, poverty, and war continued. At the beginning of the twentieth century these evils continued, but inroads were made against the problems, fostering the hope for better things to come. Advances were bound to occur, and they did: education became more universal, there was a greater abundance of commodities, there was more time for rest and leisure, and there was an even better promise for the future.

In 1976, however, a more pessimistic attitude prevails. The war to end all wars did not; other wars followed, and we still face the possibility of war. We also face the possibility of another depression, one not unlike that of the 1930s, which lasted for more than 6 years. Millions of American citizens still suffer from a lack of even the simplest commodities. The promise we felt at the beginning of the twentieth century has failed to be realized.

One of the most striking developments of modern times is the increase in the population of people over 65 years old. The reasons for this are obvious: preventive immunization, a better food supply, better hygiene, and better medical treatment in general. The span of life has widened, and a new and different problem results from man's longevity. It is in this context that Dr. Bellak writes his guide to the art and science of aging.

The Best Years of Your Life is a timely and necessary volume, although many writers have tackled the problems of aging, some more than 30 years ago (1, 2). Dr. Bellak's book is refreshingly free of post hoc propter hoc principles. He approaches the problem of aging with knowledge of the behavior of the senior citizen and of the interplay of factors affecting the individual and his environment. He avoids resorting to subliminal, subconscious, and assumed explanations.

Bellak dispels to some extent the myths surrounding aging and concludes, correctly, that the feeling of getting old is a mental state. His first 12 chapters are excellent and, in my opinion, factual. Chapter 13 and the following ones might prove to be somewhat distressing to the elderly. As a senior citizen myself, I was left with the feeling that the text is excellent for my children and relatives but not for myself. For the aged I would prefer a text with more discussion of mental hygiene. I would also like to have seen a little more emphasis on religion and the role of the religious counselor, plus more on the economic problems of the elderly. These subjects are certainly mentioned in the book, but the discussion is limited.

In my opinion, the author's most important effort in this book is the attempt to dispel the equation of age with organic brain syndrome. He also includes an unfortunately short paragraph on ECT, which has proved to be a safe and important therapeutic procedure for the old and for the young.

Research on aging has a long way to go; comparatively little knowledge is yet available. Is it possible to increase man's usefulness as well as his life span? This book represents a contribution to our knowledge. It is well constructed and delightful to read. Students, social workers, and anyone else who comes in contact with the elderly should read it.

Theory of Motivation, 2nd ed., *by Robert C. Bolles. New York, N.Y., Harper & Row, 1975, 556 pp., no price listed.*

This is the second edition of a book initially published in 1966 and well received at that time. In the current edition Bolles attempts to update his earlier work to encompass developments that have occurred during the past decade, which are reflected in his approach to behavioral research and motivational theory.

The basic outline of the book remains unchanged: the subject of motivation is viewed from a historical viewpoint. The author begins by contrasting the mechanistic and rationalistic schools of motivational thinking and then traces the evolutionary development of what he terms "empirical determinism." In many ways he sees motivational concepts as having served their purpose and therefore no longer of much intrinsic value.

Bolles devotes slightly less space to discussion of drive theory in this edition. He discusses antecedent aspects of drive, their energizing effects, associative aspects of drive, and the concept of acquired drive.

The final chapters are devoted to the concepts of primary and secondary reinforcement, which Bolles clearly feels offer a thrust toward a more meaningful explanation of behavior. In many ways motivation was a concept that grew out of a desire to explain behavior in a broad sense; until recently, however, it was largely theoretical and untestable in a laboratory setting. Bolles is not particularly dogmatic in his approach; rather, he turns toward the idea that reinforcement concepts are more valid and reproducible, serving to replace earlier theoretical models.

In many ways this book is a rather exhaustive literary review of the field, but with a limited scope. The 77-page bibliography is impressive and attests to the strength of the author's scholarship. Most of the research efforts on behavior are animal studies, primarily with rats. The aspects of emotion and conflict are not dealt with because they are not within the purview that the author has defined for himself.

The primary appeal of this book would appear to be to those concerned with experimental psychology and, to some degree, to those interested in behavioral modification. It is an admirable achievement, but it has a rather limited appeal.

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

MAY BE AN APPROPRIATE CHOICE FOR YOUR NEXT PATIENT WITH CLINICAL DEPRESSION/ANXIETY

See Brief Summary on last page of advertisement for information on adverse reactions, contraindications, warnings and precautions.

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and
ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

Proved efficacy in the treatment of clinical depression/anxiety

In the five years since its introduction, Sinequan (doxepin HCl) has objectively demonstrated its value in the treatment of clinical depression/anxiety. Clinical studies have shown Sinequan to be unsurpassed in effectiveness when compared to other tricyclic antidepressants.

In addition, Sinequan may offer certain advantages not generally seen with some other drugs of its class:

Marked antianxiety activity

In addition to its significant antidepressant activity, which is usually seen two to three weeks after initiation of therapy, Sinequan possesses marked antianxiety activity.

In double-blind comparisons between doxepin and amitriptyline,[1-3] the antidepressant effects of both drugs were comparable; however, more notable antianxiety effects were seen with doxepin. Superior antianxiety activity was reported among depressed patients treated in a crisis intervention clinic.[4]

Prompt sedative activity

Of the tricyclic antidepressants, Sinequan has been found to have one of the most prominent sedative effects.[5] This sedative property can be taken advantage of by administering the major portion of the daily dose *h.s.* Since clinically depressed/anxious patients frequently have accompanying sleep disturbances, this may be a valuable benefit.

Generally does not affect the activity of guanethidine at usual clinical doses[6]

"A new tricyclic antidepressant, doxepin, was evaluated for its ability to block the amine uptake mechanisms of the peripheral adrenergic neuron and blood platelet in man. At low doses, there was no evidence of inhibition of the amine pump." At clinical dosages up to 150 mg. per day, Sinequan can be given to man concomitantly with guanethidine and related compounds without blocking the antihypertensive effect.[6]

Cardiovascular side effects reported infrequently

In a series of double-blind comparative studies, 1706 doxepin-treated patients were evaluated for side effects. Incidence of tachycardia was associated with only 45 (2.6%) clinically depressed/anxious patients.[3]

SINEQUAN®
DOXEPIN HCl

100-mg., 50-mg., 25-mg. Capsules and
ORAL CONCENTRATE 10 mg./ml., 120-ml. (4-oz.) bottles

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, paresthesias, ataxia, and extrapyramidal symptoms.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, facial edema, photosensitization, pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, and anorexia have been reported. (See anticholinergic effects).

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice and alopecia have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, a starting dose of 25 mg. t.i.d. is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg./day to 150 mg./day.

In more severely ill patients an initial dose of 50 mg. t.i.d. may be required with subsequent gradual increase to 300 mg./day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg./day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg./day.

As an alternative regimen, the total daily dosage, up to 150 mg., may be given on a once-a-day schedule without loss of effectiveness. This dose may be given at bedtime.

Anti-anxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.

Supply. Available as capsules containing doxepin HCl equivalent to 10 mg., 25 mg., 50 mg., and 100 mg. of doxepin in bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). SINEQUAN (doxepin HCl) 25 mg. and 50 mg. also available in bottles of 5000. SINEQUAN Oral Concentrate (10 mg./ml.) is available in 120 ml. bottles with an accompanying dropper calibrated at 5 mg., 10 mg., 15 mg., 20 mg., and 25 mg. SINEQUAN Oral Concentrate should be diluted with approximately 120 ml. of water or orange juice prior to administration.

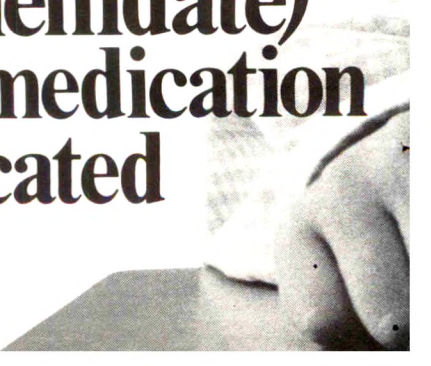
Tested by time and experience in

1962

"...a considerable decrease of hyperactivity...."[1]
Knobel, 1962

Over a decade of controlled studies and clinical experience has shown the effectiveness of Ritalin in reducing the hyperactivity,[1-3] distractibility,[1,4,5] and disorganized behavior[1-8] in the MBD child.

By lessening the effects of motor and attentional disorders, Ritalin can help the MBD child to better focus his attention on meaningful stimuli and thus can often improve cognition and promote learning.[6,9]



And side effects – insomnia and appetite loss – with Ritalin have occurred less frequently than with dextroamphetamine.[10,11]

Indeed, Ritalin is currently a drug of choice in many MBD situations,[10,12] and can prove to be an important element in many complete remedial programs for MBD.

Therapy with Ritalin should be undertaken only after a medical diagnosis of MBD has been made. Drug treatment is not indicated for all children with MBD.

Dosage should be periodically interrupted. Often, these interruptions reveal some "stabilization" in the child's behavior even without medication, permitting a reduction in dosage and eventual discontinuance of drug therapy.

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources.

Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available. Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative.

Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, or, if necessary, discontinue the drug.

Ritalin should be periodically discontinued to assess the child's condition. Improvement may be sustained when the drug is either temporarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 100 and 1000.

Tablets, 10 mg (pale green, scored); bottles of 100, 500, 1000 and Accu-pak® blister units of 100.

Tablets, 5 mg (pale yellow); bottles of 100, 500, and 1000.

Consult complete product literature before prescribing.

In depression

Daily Dosage Chart

1 h.s.

A major reason for drug defaulting is multiple daily dosage schedules.

Ayd* reports that 70 percent of patients default on a q.i.d. regimen; 60 percent on t.i.d.; 30 percent on b.i.d., and only 7 percent on a single daily dose.

A single daily capsule that provides a full day's medication would logically assure better therapeutic results.

Because one capsule lasts from bedtime to bedtime, Tofranil-**PM**® may markedly reduce the probability of missed doses.

After therapy is initiated with the 75-mg. capsule, the 150-mg. capsule is the dose level at which optimum response is usually obtained.

Please review the prescribing information summarized on the back of this page.

*Ayd, F.J., Jr. (Ed.): Int. Drug Ther. Newslett. 7(9/10):35-50 (Nov./Dec.) 1972.

Tofranil-PM®
imipramine pamoate

One capsule
lasts from bedtime
to bedtime.

Initial Dose

For Maintenance Therapy

Starting Dose	Usual Optimum Response Dose	A Full Range to Choose From*			
					
75 mg.	150 mg.	150 mg.	125 mg.	100 mg.	75 mg.

*Each capsule contains imipramine pamoate equivalent to 150, 125, 100 or 75 mg. imipramine hydrochloride.

Tofranil-PM®
brand of imipramine pamoate

Indications: For the relief of symptoms of depression. Endogenous depression is more likely to be alleviated than other depressive states.

Contraindications: The concomitant use of monoamine oxidase inhibiting compounds is contraindicated. Hyperpyretic crises or severe convulsive seizures may occur in patients receiving such combinations. The potentiation of adverse effects can be serious, or even fatal. When it is desired to substitute Tofranil-PM, brand of imipramine pamoate, in patients receiving a monoamine oxidase inhibitor, as long an interval should elapse as the clinical situation will allow, with a minimum of 14 days. Initial dosage should be low and increases should be gradual and cautiously prescribed. The drug is contraindicated during the acute recovery period after a myocardial infarction. Patients with a known hypersensitivity to this compound should not be given the drug. The possibility of cross-sensitivity to other dibenzazepine compounds should be kept in mind.

Warnings: *Usage in Pregnancy:* Safe use of imipramine during pregnancy and lactation has not been established; therefore, in administering the drug to pregnant patients, nursing mothers, or women of childbearing potential, the potential benefits must be weighed against the possible hazards. Animal reproduction studies have yielded inconclusive results. There have been clinical reports of congenital malformation associated with the use of this drug, but a causal relationship has not been confirmed.

Extreme caution should be used when this drug is given to:

—patients with cardiovascular disease because of the possibility of conduction defects, arrhythmias, myocardial infarction, strokes and tachycardia;

—patients with increased intraocular pressure, history of urinary retention, or history of narrow-angle glaucoma because of the drug's anticholinergic properties;

—hyperthyroid patients or those on thyroid medication because of the possibility of cardiovascular toxicity;

—patients with a history of seizure disorder because this drug has been shown to lower the seizure threshold;

—patients receiving guanethidine or similar agents since imipramine may block the pharmacologic effects of these drugs.

Since imipramine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as operating an automobile or machinery, the patient should be cautioned accordingly.

Usage in Children: Tofranil-PM, brand of imipramine pamoate, should not be used in children of any age because of the increased potential for acute overdosage due to the high unit potency (75 mg., 100 mg., 125 mg. and 150 mg.). Each capsule contains imipramine pamoate equivalent to 75 mg., 100 mg., 125 mg. or 150 mg. imipramine hydrochloride.

Precautions: It should be kept in mind that the possibility of suicide in seriously depressed patients is inherent in the illness and may persist until significant remission occurs. Such patients should be carefully supervised during the early phase of treatment with Tofranil-PM, brand of imipramine pamoate, and may require hospitalization. Prescriptions should be written for the smallest amount feasible.

Hypomanic or manic episodes may occur, particularly in patients with cyclic disorders. Such reactions may necessitate discontinuation of the drug. If needed, Tofranil-PM, brand of imipramine pamoate, may be resumed in lower dosage when these episodes are relieved. Administration of a tranquilizer may be useful in controlling such episodes.

Prior to elective surgery, imipramine should be discontinued for as long as the clinical situation will allow.

An activation of the psychosis may occasionally be observed in schizophrenic patients and may require reduction of dosage and the addition of a phenothiazine.

In occasional susceptible patients or in those receiving anticholinergic drugs (including antiparkinsonism agents) in addition, the atropine-like effects may become more pronounced (e.g., paralytic ileus). Close supervision and careful adjustment of dosage is required when this drug is administered concomitantly with anticholinergic or sympathomimetic drugs.

Avoid the use of preparations, such as decongestants and local anesthetics, which contain any sympathomimetic amine (e.g., adrenalin, noradrenalin), since it has been reported that tricyclic antidepressants can potentiate the effects of catecholamines.

Patients should be warned that the concomitant use of alcoholic beverages may be associated with exaggerated effects.

Both elevation and lowering of blood sugar levels have been reported.

Concurrent administration of imipramine with electroshock therapy may increase the hazards; such treatment should be limited to those patients for whom it is essential, since there is limited clinical experience.

Adverse Reactions: Note: Although the listing which follows includes a few adverse reactions which have not been reported with this specific drug, the pharmacological similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when imipramine is administered.

Cardiovascular: Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke, falls.

Psychiatric: Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurological: Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic: Dry mouth, and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic: Skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight); edema (general or of face and tongue); drug fever; cross-sensitivity with desipramine.

Hematologic: Bone marrow depression including agranulocytosis; eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathological neutrophil depression.

Gastrointestinal: Nausea and vomiting, anorexia, epigastric distress, diarrhea; peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache and malaise.

Dosage and Administration: In adult outpatients, therapy should be initiated on a once-a-day basis with 75 mg./day. This may be increased to 150 mg./day which is the dose level which usually obtains optimum response. If necessary, dosage may be increased to 200 mg./day. Dosage should be modified as necessary by clinical response and any evidence of intolerance. Daily dosage may be given at bedtime, or in some patients in divided daily doses.

Hospitalized patients should be started on a once-a-day basis with 100-150 mg./day and may be increased to 200 mg./day. Dosage should be increased to 250-300 mg./day if there is no response after two weeks.

Following remission, maintenance medication may be required for a longer period of time at the lowest dose that will maintain remission. The usual adult maintenance dosage is 75-150 mg./day on a once-a-day basis, preferably at bedtime.

In adolescent and geriatric patients, capsules of Tofranil-PM, brand of imipramine pamoate, may be used when total daily dosage is established at 75 mg. or higher. It is generally unnecessary to exceed 100 mg./day in these patients. This dosage may be given once a day at bedtime or, if needed, in divided daily doses.

How Supplied: Tofranil-PM, brand of imipramine pamoate: Capsules of 75, 100, 125 and 150 mg. (Each capsule contains imipramine pamoate equivalent to 75, 100, 125 or 150 mg. of imipramine hydrochloride.)

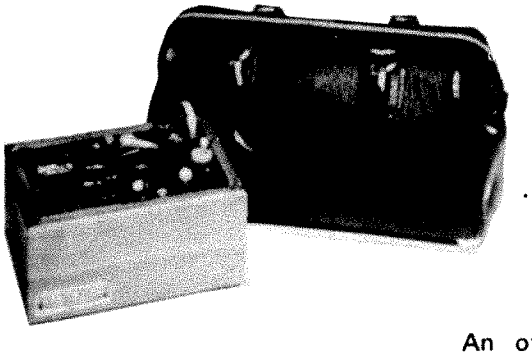
MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

in clinically significant depression...

penetrating the symptom barrier to productive psychotherapy

symptoms often interfere with therapy

In clinically significant depression, the patient often becomes barricaded behind his own symptoms during psychotherapy. Because these symptoms can be so sharply defined and somatic in expression, he may reject the fact that they are psychic in origin. Sleep disturbance, gastrointestinal complaints, anorexia, chronic fatigue, and other psychosomatic symptoms may so preoccupy—or overwhelm—the depressed patient that truly productive therapeutic sessions are difficult to achieve. Instead of being able to concentrate on the core emotional problems of the depression itself, he may for example go on at length about how broken his sleep is or keep reiterating (while the therapeutic hour slips by) how physically miserable he feels.

ELAVIL®
(AMITRIPTYLINE HCl, MSD)
to help penetrate the symptom barrier in depression requiring medication

ELAVIL, a highly effective tricyclic antidepressant, will often alleviate these symptoms. With the help of ELAVIL, sleep disturbance—so common in clinically depressed patients and often the symptom that distresses them most—as

well as other "barrier symptoms" may be lessened to the point where they no longer come between you and the patient.

psychotherapy takes direction

As these preoccupying complaints are lifted, psychotherapy sessions can become more productive. Patients are enabled to respond more fruitfully during therapeutic hours and to resume or pursue more efficiently the necessary activities in their personal lives.

meeting therapeutic goals

And as the antidepressant activity of ELAVIL (Amitriptyline HCl, MSD) takes hold, it helps relieve the depressive condition itself. Sometimes only a minimum of actual psychotherapy is required. The patient may experience a more rapid recovery—while you conserve valuable time.

Prescribe ELAVIL then, to help lighten the patient's burden in depression—and yours in its management.

ELAVIL should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Its safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, and 100 mg
INJECTION: 10 mg per ml

ELAVIL®

(AMITRIPTYLINE HCl | MSD)

an antidepressant with an anxiety-reducing sedative component to its action

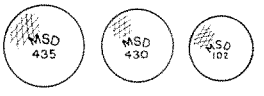
MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information, please see following page.

MSD
MERCK SHARP & DOHME

addendum

ELAVIL®



(AMITRIPTYLINE HCl | MSD)

Five tablet strengths for differing patient needs. The variety of dosage strengths available with ELAVIL makes possible great prescribing flexibility.

Once-a-day dosage at bedtime is an appropriate way to start—and maintain—many patients on therapy. The simplicity of this regimen helps improve patient compliance. ELAVIL may also be prescribed in divided daily doses.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.

100 mg
75 mg
50 mg

These tablets may be advantageous when initiating therapy with once-daily bedtime dosage in adult outpatients. The usual starting dosage is 75 mg daily. Therapy may be initiated with 50 to 100 mg daily. This may be increased by 25 or 50 mg as necessary in the bedtime dose to a total of 150 mg per day.

These tablets may also be convenient for many hospitalized patients. These patients may need 100 mg a day initially which can be increased gradually to 200 mg a day if necessary. A small number of such patients may need as much as 300 mg a day.

25 mg

This tablet may prove useful when initiating therapy with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime doses.

10 mg

Because lower doses are generally recommended for adolescents and elderly patients, the 10-mg tablets may be most serviceable. Ten mg three times a day with 20 mg at bedtime may be satisfactory in adolescent and elderly patients who do not tolerate higher doses.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor or within at least 14 days following the discontinuance of a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and lactation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

MSD
MERCK SHARP & DOHME

a valuable link to the resources of the American Psychiatric Association

for institutions and agencies concerned with the care of the mentally disabled

Enrollment in the Hospital & Community Psychiatry Service brings multiple copies of *Hospital & Community Psychiatry* into member agencies every month, keeping staff up to date on developments and issues in the mental health field, offering new ideas and fresh perspectives, and serving as a useful resource in staff development and training programs.

Hospital & Community Psychiatry is just one of the benefits of membership in the H&CP Service. Others include a film library containing more than a hundred films specially chosen for their usefulness in staff development and community education programs; supplementary mailings of important books, reports, articles, or other material of special interest to administrators or clinicians; reduced registration fees at the annual fall Institute on Hospital & Community Psychiatry; and, on request, information and consultation from the professional staff of the American Psychiatric Association. The H&CP Service also sponsors the annual Achievement Awards competition, which gives special recognition to outstanding programs for the mentally ill and mentally retarded.

Please send me information about membership in the Hospital & Community Psychiatry Service.

What can a long-acting injectable phenothiazine do that a short-acting oral can't?

It can save time, it can save money, and it can even save people – by reducing readmissions.

Time Prolixin Decanoate (Fluphenazine Decanoate Injection), with duration of action that may last up to 4 weeks or longer in patients on maintenance therapy, can effect important savings in nursing time.

Approximate Staff Time Required to Medicate 18 Schizophrenic Patients*

8 a.m. ¾ hr. 1 p.m. ¾ hr. 6 p.m. ¾ hr.	1 injection every 28 days for most patients
= 2¼ hours nursing time	4 minutes required for each injection
2¼ hrs. x 28 days = 63 hours of nursing time every 28 days	= 1 hr., 10 minutes nursing time in 28 days
NURSING TIME SAVED IN 28 DAYS	61 hours and 50 minutes or more than 7½ eight-hour working days

*Adapted from Platt R: Br J Social Psychiatry 2: 187-191, 1968.

Money Martin and Townend[1], who found from their study of Prolixin Decanoate that 15 of 39 patients could be maintained on 25 mg. every 4 weeks, also note that on this basis "a year's maintenance on chlorpromazine represents the order of 110 grams of phenothiazine as opposed to 0.33 gram of fluphenazine." Translating this into dollars shows the following potential hospital savings on the basis of patient population:

Agent and amount/year	Form	Cost/patient/year	Cost/500 patients/year
Chlorpromazine (SKF brand) 110 grams	8 oz. concentrate 100 mg./ml.†	$48.75*	$24,375
Prolixin Decanoate .33 grams	5 ml. vials 25 mg./ml.	23.17**	11,585
SAVINGS		$25.58 patient, year	$12,790 500 pts/yr.

* Calculated from prices published in 1975 Red Book.
** Calculated from Squibb 1975 price catalogue.
† With tablets, the annual cost is even greater.

People The controlled drug delivery system of Prolixin Decanoate helps get schizophrenic patients out of the hospital and helps them stay out. It promotes continuity of therapy—reducing outpatient drug defaulting from approximately 50% with oral medications according to one report[2] to about 16% according to another report[3].

It reduces the number and length of rehospitalizations. In one study of 103 patients maintained on injections of long-acting fluphenazines, total hospital readmissions for a year were cut from 191 to 50 and inpatient time from 8,713 days to 1,335 days[4].

It facilitates return to a productive life. A 12-month followup of 103 discharged patients revealed 77% in full-time employment or household duties and only 23% unemployed[4].

PROLIXIN DECANOATE®

(Fluphenazine Decanoate Injection)

may control schizophrenic symptoms for up to 4 weeks or longer in patients on maintenance therapy.

SQUIBB® "The Priceless Ingredient of every product is the honor and integrity of its maker." ™

For product brief summary see following page.

H425-001R

PROLIXIN DECANOATE®

(Fluphenazine Decanoate Injection)

may control schizophrenic symptoms for up to 4 weeks or longer in patients on maintenance therapy.

Prolixin Decanoate (Fluphenazine Decanoate Injection) provides 25 mg. fluphenazine decanoate per ml. in a sesame oil vehicle with 1.2% (w/v) benzyl alcohol as a preservative.

CONTRAINDICATIONS: In presence of suspected or established subcortical brain damage. In patients who have a blood dyscrasia, liver damage or renal insufficiency, or who are receiving large doses of hypnotics, or who are comatose or severely depressed. In patients who have shown hypersensitivity to fluphenazine; cross-sensitivity to phenothiazine derivatives may occur.

Not intended for use in children under 12.

WARNINGS: Mental and physical abilities required for driving a car or operating heavy machinery may be impaired by use of this drug. Physicians should be alert to the possibility that severe adverse reactions may occur which require immediate medical attention. Potentiation of effects of alcohol may occur. Safety and efficacy in children have not been established because of inadequate experience in use in children.

Usage in Pregnancy: Safety for use during pregnancy has not been established; weigh possible hazards against potential benefits if administering this drug to pregnant patients.

PRECAUTIONS: Caution must be exercised if another phenothiazine compound caused cholestatic jaundice, dermatoses or other allergic reactions because of the possibility of cross-sensitivity. When psychotic patients on large doses of a phenothiazine drug are to undergo surgery, hypotensive phenomena should be watched for; less anesthetics or central nervous system depressants may be required. Because of added anticholinergic effects, fluphenazine may potentiate the effects of atropine.

Use fluphenazine decanoate cautiously in patients exposed to extreme heat or phosphorus insecticides; in patients with a history of convulsive disorders since grand mal convulsions have occurred; and in patients with special medical disorders such as mitral insufficiency or other cardiovascular diseases, and pheochromocytoma. Bear in mind that with prolonged therapy there is the possibility of liver damage, pigmentary retinopathy, lenticular and corneal deposits, and development of irreversible dyskinesia.

Fluphenazine decanoate should be administered under the direction of a physician experienced in the clinical use of psychotropic drugs. Periodic checking of hepatic and renal functions and blood picture should be done. Renal function of patients on long-term therapy should be monitored; if BUN becomes abnormal, treatment should be discontinued. "Silent pneumonias" are possible.

ADVERSE REACTIONS: *Central Nervous System*—Extrapyramidal symptoms are most frequently reported. These include pseudoparkinsonism, dystonia, dyskinesia, akathisia, oculogyric crises, opisthotonos, and hyperreflexia; most often these are reversible, but they may be persistent. One can expect a higher incidence of such reactions with fluphenazine decanoate than with less potent piperazine derivatives or straight-chain phenothiazines. The incidence and severity will depend more on individual patient sensitivity, but dosage level and patient age are also determinants. As these reactions may be alarming, the patient should be forewarned and reassured. These reactions can usually be controlled by administration of antiparkinsonian drugs such as benztropine mesylate or intravenous Caffeine and Sodium Benzoate Injection U.S.P., and by subsequent reduction in dosage.

Persistent Tardive Dyskinesia: As with all antipsychotic agents, persistent and sometimes irreversible tardive dyskinesia may appear in some patients on long-term therapy or may occur after discontinuation of drug. The risk seems greater in elderly patients, especially females, on high dosages. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and may be accompanied by involuntary movements of extremities. There is no known effective therapy for tardive dyskinesia; usually the symptoms are not alleviated by antiparkinsonism agents. If the symptoms appear, discontinuation of all antipsychotic agents is suggested. The syndrome may be masked if treatment is reinstituted, or drug dosage increased, or a different antipsychotic agent used. Reports are that fine vermicular movements of the tongue may be an early sign of the syndrome which may not develop if medication is stopped at that time.

Phenothiazine derivatives have been known to cause restlessness, excitement, or bizarre dreams; reactivation or aggravation of psychotic processes may be encountered. If drowsiness or lethargy occur, the dosage may have to be reduced. Dosages, far in excess of the recommended amounts, may induce a catatonic-like state.

Autonomic Nervous System—Hypertension and fluctuations in blood pressure have been reported. Although hypotension is rarely a problem, patients with pheochromocytoma, cerebral vascular or renal insufficiency or severe cardiac reserve deficiency such as mitral insufficiency appear to be particularly prone to this reaction and should be observed carefully. Supportive measures including intravenous vasopressor drugs should be instituted immediately should severe hypotension occur; Levarterenol Bitartrate Injection U.S.P. is the most suitable drug; *epinephrine should not be used* since phenothiazine derivatives have been found to reverse its action. Nausea, loss of appetite, salivation, polyuria, perspiration, dry mouth, headache and constipation may occur. Reducing or temporarily discontinuing the dosage will usually control these effects. Blurred vision, glaucoma, bladder paralysis, fecal impaction, paralytic ileus, tachycardia, or nasal congestion have occurred in some patients on phenothiazine derivatives.

Metabolic and Endocrine—Weight change, peripheral edema, abnormal lactation, gynecomastia, menstrual irregularities, false results on pregnancy tests, impotency in men and increased libido in women have occurred in some patients on phenothiazine therapy.

Allergic Reactions—Itching, erythema, urticaria, seborrhea, photosensitivity, eczema and exfoliative dermatitis have been reported with phenothiazines. The possibility of anaphylactoid reactions should be borne in mind.

Hematologic—Blood dyscrasias including leukopenia, agranulocytosis, thrombocytopenic or nonthrombocytopenic purpura, eosinophilia, and pancytopenia have been observed with phenothiazines. If soreness of the mouth, gums or throat or any symptoms of upper respiratory infection occur and confirmatory leukocyte count indicates cellular depression, therapy should be discontinued and other appropriate measures instituted immediately.

Hepatic—Liver damage manifested by cholestatic jaundice, particularly during the first months of therapy, may occur; treatment should be discontinued. A cephalin flocculation increase, sometimes accompanied by alterations in other liver function tests, has been reported in patients who have had no clinical evidence of liver damage.

Others—Sudden deaths have been reported in hospitalized patients on phenothiazines. Previous brain damage or seizures may be predisposing factors. High doses should be avoided in known seizure patients. Shortly before death, several patients showed flare-ups of psychotic behavior patterns. Autopsy findings have usually revealed acute fulminating pneumonia or pneumonitis, aspiration of gastric contents, or intramyocardial lesions. Although not a general feature of fluphenazine, potentiation of central nervous system depressants such as opiates, analgesics, antihistamines, barbiturates, and alcohol may occur.

Systemic lupus erythematosus-like syndrome, hypotension severe enough to cause fatal cardiac arrest, altered electrocardiographic and electroencephalographic tracings, altered cerebrospinal fluid proteins, cerebral edema, asthma, laryngeal edema, and angioneurotic edema; with long-term use, skin pigmentation and lenticular and corneal opacities have occurred with phenothiazines. Local tissue reactions occur only rarely with injections of fluphenazine decanoate.

For full prescribing information, consult package insert.

HOW SUPPLIED: 1 ml. Unimatic® single dose preassembled syringes and cartridge-needle units, and 5 ml. vials.

A Timely New Book from The Joint Information Service

This latest Joint Information Service field study provides a concise, comprehensive overview of the complex matter of the very young American child and his mental health, and then describes in intimate detail seven unique programs for pre-school children with problems—from North Hollywood's Dubnoff Center, emphasizing education as its primary therapeutic modality, to Baltimore's Martin Luther King, Jr. Parent-Child Center, serving two housing projects, served by Johns Hopkins, and largely governed by its own people. All different in treatment approach and philosophy, the programs described are uniform in their dedication to innovation in improving service to the emotionally disturbed very young child, and, equally, to the emotional well being of all young children.

This thoughtful and perceptive description of what has been created by some of the best informed, most experienced and thoughtful specialists in mental health services for very young children should be welcome to all involved in the mental health of children and a casebook for those dealing with child and family mental health.

An articulate exposition of the immense problems and encouraging accomplishments in a particularly difficult area of endeavor . . . . Beyond their concern with the manifestly ill child, the authors intriguingly explore what may be needed to enhance the mental good health of all young children . . . . A significant contribution.

James N. Sussex, M.D.
President, American Association of Psychiatric Services for Children

'STELAZINE' PROVIDES EFFECTIVE CONTROL OF HALLUCINATIONS, DELUSIONS, ANXIETY AND OTHER PSYCHOTIC SYMPTOMS.
BECAUSE IT APPEARS TO HAVE AN ACTIVATING EFFECT, 'STELAZINE' IS ESPECIALLY USEFUL IN WITHDRAWN, APATHETIC OR DETACHED PATIENTS.

- CONTROLS PSYCHOTIC SYMPTOMS
- SELDOM CAUSES EXCESSIVE SEDATION
- CONVENIENT B.I.D. DOSAGE

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

INDICATIONS

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F Co.) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

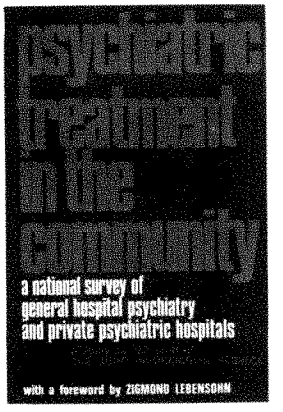
TRIFLUOPERAZINE HCL



HELPS WITHDRAWN PATIENTS BECOME MORE RESPONSIVE.

Where The Action Is—

For more than a decade the general hospital psychiatric unit has been the principal locus of inpatient treatment. This latest Joint Information Service national survey brings up to date its earlier—and the original—study of this important component of the psychiatric scene. It reveals that the remarkable rate of growth held up, showing an increase of 50 percent in the number of units between 1963 and 1971, and an increase of 46 percent in the number of admissions. And it verifies that general hospital psychiatry has become increasingly comprehensive, with an impressively high level of outpatient service, emergency service, and even consultation to community agencies. Indeed, the general hospital accounts for several times as much service and activity as the widely heralded federally supported community mental health center.

This study also involves the private psychiatric hospitals, which have not changed much in number but are admitting about 10,000 more patients than in 1964—and they, too, are providing a remarkably comprehensive program.

It's your responsibility to be well-informed about these extraordinarily significant and vital pieces of American psychiatric service. You can do so by sending the order form below.

Out of touch

but not beyond reach...

Help restore reality

- low dose, high potency phenothiazine useful for inpatient and outpatient treatment
- helps orient psychiatric patients to their surroundings
- effective with minimal sedation, usually produces little lethargy or drowsiness

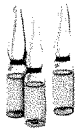
Trilafon®
brand of
perphenazine, NF
for management of disturbed behavior in schizophrenic and manic states

Versatile Dosage	
Injection	5 mg/ml, 1 ml ampul
Concentrate	16 mg/5 ml, 120 ml bottle
Tablets	2,4,8,16 mg
REPETABS® Tablets 8 mg brand of repeat-action tablets	

Please see next page for prescribing information.

Trilafon®
brand of perphenazine, NF

For management of schizophrenic and manic disorders in psychiatric hospitals, mental health clinics, and with outpatient treatment



TABLETS
for maintenance or control of patients in hospital or home

BENEFITS
- generally improve cooperation and communication
- decrease need for custodial care, hasten discharge

CONCENTRATE
for maintenance or control of uncooperative in-hospital patients

- easily mixes with most liquids
- ensures easy, steady, certain administration

INJECTION
for emergency control of uncooperative in-hospital patients

- usually takes effect in 10 minutes
- average duration of effect is 6 hours

TRILAFON® Tablets
brand of perphenazine, NF

REPETABS® Tablets
Concentrate
Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON **Injection** should not be given to patients in coma or severely depressed states.

WARNINGS **Dosage in pregnancy:** Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operating machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenazine should be under medical supervision, particularly if they are receiving high doses. Patients who have had any severe reaction to phenothiazines or to imipramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patients treated with perphenazine, the possibility that they might occur with TRILAFON should be considered: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the visual fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyphagia; photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, but not epinephrine, because epinephrine's action is blocked and partly reversed by perphenazine. Severe, acute hypotension has occurred with the use of phenothiazines and is of particular concern in patients with mitral insufficiency or pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic reaction to perphenazine; treatment with perphenazine should be stopped if this occurs.

The antiemetic effect of perphenazine can obscure signs of toxicity due to overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor or intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefore, contact of hands or clothing by those handling perphenazine solutions should be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-system-depressant actions of opiates, antihistamines, barbiturates, and alcohol, less than the usual dosage of these agents is required when they are administered concomitantly with TRILAFON. Patients should be cautioned that their response to alcohol may be increased while they are being treated with TRILAFON.

Phenothiazines also potentiate the effects of atropine, heat, and phosphorus insecticides, and should be used with caution in persons exposed to these agents.

ADVERSE REACTIONS *Extrapyramidal reactions:* dystonia including protrusion, discoloration, aching and rounding of the tongue; tonic spasm of the masticatory muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric crisis, trismus, torticollis, retrocollis, muscle weakness, and aching and numbness of the limbs; akathisia; motor restlessness; dyskinesia, parkinsonism; hyperreflexia; and ataxia. The incidence and severity of these reactions usually increase with increased dosage, but have occurred in some patients receiving low dosage. Reduction in dosage or treatment with an antispasmodic agent will usually control extrapyramidal reactions. In some instances, however, these reactions may persist after discontinuation of treatment with perphenazine.

Persistent tardive dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities. There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine, vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON **Injection** have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON (perphenazine) **Injection** is a rare occurrence.

LIBRIUM®
(chlordiazepoxide HCl)
5 mg, 10 mg, 25 mg capsules

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

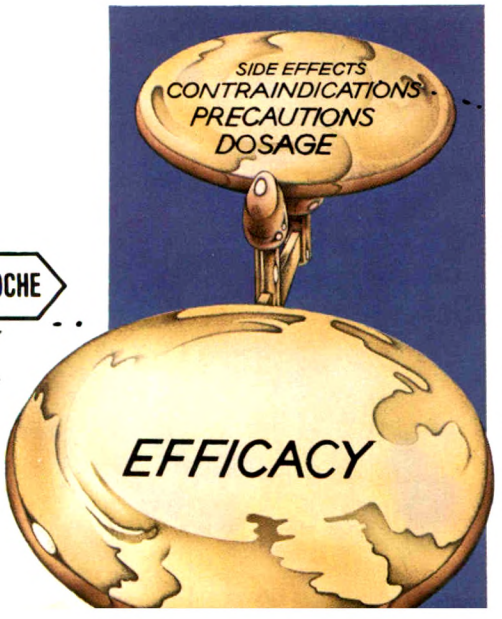
Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported Also encountered are isolated instances skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fa activity) may appear during and after tre ment; blood dyscrasias (including agran locytosis), jaundice and hepatic dysfun have been reported occasionally, makir periodic blood counts and liver functior tests advisable during protracted therap

Supplied: Librium® Capsules containir 5 mg, 10 mg or 25 mg chlordiazepoxide HCl. Libritabs® Tablets containing 5 m 10 mg or 25 mg chlordiazepoxide.

ROCHE
Roche Laboratories
Division of Hoffmann-La Roche
Nutley, New Jersey 07110

SAFETY. IT'S A QUESTION OF BALANCE.

In choosing a tranquilizer for the patient whose excessive anxiety is disrupting psychotherapy there are a number of things to consider. One is effectiveness. A second is safety.



The first is more easily established. The second may be ascertained by comparison. In other words, with safety there is the question of balancing a drug's potential benefits against any potential risks.

When the antianxiety agent you are considering is Librium, you should know that it has a wide margin of safety.

The most common side effects of Librium are dose-related and thus largely avoidable. There appears to be a low incidence of drug dependence and tolerance. Librium rarely has any adverse effects on the cardiovascular or respiratory systems, and there are relatively few cases of known toxicity attributable to Librium.

You already know that Librium is effective. But you should also know that Librium, used in proper dosage, rarely interferes with mental acuity and thus is unlikely to interfere with the psychotherapeutic process. In addition, Librium is used concomitantly with many primary medications.

Librium. All in all, a very good balance.
